How to Find Product Data in This Reference Manual

THIS IS VOLUME II OF THE DATA CONVERTER REFERENCE MANUAL

It and its companion volume contain Data Sheets, Selection Guides and a wealth of background information on signal conversion and a wide variety of components for mixed signal processing.

It is one member of a four-volume set of reference manuals describing and specifying Linear, Converter and Audio/Video products from Analog Devices, Inc., in IC, hybrid and assembled form for measurement, control and real-world signal processing.

IF YOU KNOW THE MODEL NUMBER

Turn to the product index at the back of the book and look up the model number. You will find the Volume-Section-Page location of any data sheet in this volume or Volume I. You will find additional references for product categories not included in the *Data Converter Reference Manual*.

If you're looking for a form-and-function-compatible version of a product originally brought to market by some other manufacturer (second source), you may find it by adding our "AD" prefix and looking it up in the index. Or call our nearest sales office.

IF YOU DON'T KNOW THE MODEL NUMBER

Find your functional group in the list on the opposite page, or in the listing for Volume I below. Turn directly to the appropriate Section. You will find a functional Selection Guide at the beginning of the Section. The Selection Guide (and the "Orientation" that usually accompanies it) will help you find the products that are the closest to satisfying your need. Use them to compare all products in the category by salient criteria. A comprehensive Table of Contents (of this volume) is provided for your convenience on pages 1–5 through 1–10.

IF YOU CAN'T FIND IT HERE OR IN VOLUME I . . . ASK!

If it's not a signal conversion product, it's probably in one of the two companion volumes, the *Linear Products Reference Manual* or the *Audio/Video Products Reference Manual*. If you don't already own these volumes, you can have them FREE by getting in touch with Analog Devices or the nearest sales office, or phoning 1-800-262-5643.

See the Worldwide Sales Directory on pages 12–12 and 12–13 at the back of this volume for our sales office phone numbers.

Contents of Other Reference Manuals

AUDIO/VIDEO PRODUCTS

- Operational Amplifiers
- Audio A/D Converters
- Video A/D Converters
- Audio D/A Converters
- Video D/A Converters
- Special Function Audio Products
- Special Function Video Products
- Digital Signal Processing Products
- Application Notes

DATA CONVERTER PRODUCTS (VOLUME I)

- D/A Converters
- S/D Converters
- Communications Products
- Digital Panel Meters
- Digital Signal Processing Products
- Bus Interface & Serial I/O Products
- Application Specific ICs
- Power Supplies

LINEAR PRODUCTS

- Operational Amplifiers
- Comparators
- Instrumentation Amplifiers
- Isolation Amplifiers
- Analog Multipliers/Dividers
- Log/Antilog Amplifiers
- RMS-to-DC Converters
- Mass Storage Components
- ATE Components
- Special Function Components
- Temperature Transducers
- Signal Conditioning Components & Subsystems
- Digital Panel Instruments
- Bus Interface & Serial I/O Products
- Automotive Components
- Application Specific ICs
- Power Supplies
- Component Test Systems

Introduction 1–3
Table of Contents 1–5

1

Introduction

Analog Devices designs, manufactures and sells worldwide sophisticated electronic components and subsystems for use in real-world signal processing. More than six hundred standard products are produced in manufacturing facilities located throughout the world. These facilities encompass all relevant technologies, including several embodiments of CMOS, BiMOS, bipolar and hybrid integrated circuits, each optimized for specific attributes—and assembled products in the form of potted modules, printed-circuit boards and instrument packages.

State-of-the-art technologies (including surface micromachining) have been utilized (and in many cases invented) to provide timely, reliable, easy-to-use advanced designs at realistic prices. Our popular IC products are available in both conventional and surface-mount packages (SOIC, LCC, PLCC), and many of our assembled products employ surface-mount technology to reduce manufacturing costs and overall size. A quarter-century of successful applications experience and continuing vertical integration insure that these products are oriented to user needs. The ongoing application of today's state-of-the-art and the invention of tomorrow's state-of-the-art processes strengthen the leadership position of Analog Devices in standard data-acquisition and signal-processing products and make us a strong contender in high performance mixed-signal ASICs.

MAJOR PROGRESS

Since publication of the selection guides in the *1990 Databook Series*, more than 120 significant new products have been introduced by Analog Devices; they run the gamut from brand new product categories and technologies to new standard products (with improvements in price, performance or design) to augmented second-source products. In addition, the Analog Devices line of IC products now includes the products of Precision Monolithics, Inc., which was acquired by Analog Devices in 1990. The new products are all classified and summarized in these volumes, along with existing products that are desirable for use in new designs.

Examples of the variety and innovation content of outstanding new ICs to be found in these two volumes include:

- the ADV7141/46/48 Edsun CEG/DAC™ family of monolithic RAM-DACs, designed to eliminate "jaggies" and improve color resolution in VGA displays (Vol. I)
- the AD28msp02 16-bit codec, a complete analog front end for high-performance voiceband DSP applications (Vol. I)
- the DAC-8800 and -8840 TrimDACs™, which eliminate pots and permit automatic trimming of offsets and gains in electronic circuits and systems (Vol. I)
- the AD7710/11/12 family of 21-bit sigma-delta a/d converters with complete on-chip signal conditioning (Vol. II)
- the AD9100 wideband low-distortion monolithic track-hold amplifier with 13 ns acquisition time to 0.1% (Vol. II)
- the AD1674 12-bit sampling a/d converter, a "faster, better, cheaper" upgrade for AD574/674/774 a/d converter sockets (Vol. II)
- the AD9020/9060 10-bit TTL/ECL flash a/d converters with sampling rates to 75 MSPS (Vol. II)
- the AD671 12-bit, 500 ns a/d converter (Vol. II).

Many more could have been added to this list.

CEG/DAC, TrimDAC and DSPatch are trademarks of Analog Devices, Inc.

2-VOLUME DATA CONVERTER REFERENCE MANUAL

This two-volume set provides comprehensive technical data on Analog Devices data-conversion products, which are involved in spanning the interface between analog and digital worlds. It is a companion to the *Linear Products Databook*, which provides similar data for analog-to-analog products. Both volumes contain:

- comprehensive data sheets and package information on a total of more than 350 significant product families
- orientation material and selection guides for finding products rapidly
- a representative list of available Analog Devices technical publications on real-world analog and digital signal processing
- our Worldwide Sales Directory
- the complete Product Index to all data-conversion and DSP products listed in these two volumes and all products listed in the Linear Products Databook.

Division of Product Groups between the Two Books

Volume I contains information on
- Digital-to-analog converters
- Synchro/resolver-to-digital converters
- Communications products
- Digital panel meters
- Digital signal processing products
- Bus interface and serial I/O products
- Application specific ICs
- Power supplies.

Volume II contains information on:
- Analog-to-digital converters
- Voltage-to-frequency and frequency-to-voltage converters
- Sample/track-hold amplifiers
- Switches and multiplexers
- Voltage references
- Data acquisition subsystems
- Analog I/O ports
- Application-specific ICs
- Power supplies.

The product data in this book are intended primarily for the majority of users who are concerned with new designs. For this reason, existing and available products that offer little if any unique advantage over newer products in future designs are listed in the Index, and data sheets may be available separately—but they are not published in this book.

TECHNICAL SUPPORT

Our extensive technical literature discusses the technology and applications of products for real-world signal processing. Besides tutorial material and comprehensive data sheets, including a large number in our Databooks, we offer Application Notes, Application Guides, Technical Handbooks (at reasonable prices), and several free serial publications; for example, *Analog Productlog* provides brief information on new products being introduced, and *Analog Dialogue*, our technical magazine, provides in-depth discussions of new developments in analog and digital circuit technology as applied to data acquisition, signal processing, control, and test. *DSPatch*™ is a quarterly newsletter that brings its readers up-to-date applications information on

our DSP products and the general field of digital signal processing. We maintain a mailing list of engineers, scientists, and technicians with a serious interest in our products. In addition to Databook catalogs—and general short-form selection guides—we also publish several short-form catalogs on specific product families. You will find typical publications described on pages 12–8 to 12–11 at the back of the book.

SALES AND SERVICE

Backing up our design and manufacturing capabilities and our extensive array of publications, is a network of distributors, plus sales offices and representatives throughout the United States and most of the world, staffed by experienced sales and applications engineers. Our Worldwide Sales Directory, as of the publication date, appears on pages 12–12 and 12–13 at the back of the book.

RELIABILITY

The manufacture of reliable products is a key objective at Analog Devices. The primary focus is the companywide Quality Improvement Process (QIP). In addition, we maintain facilities that have been qualified under such standards as MIL-M-38510 (Class B and Class S) for ICs in the U.S. and MIL-STD-1772 for hybrids. Many of our product —both proprietary and second-source—have qualified for JAN part numbers; others are in the process. A larger number of products—including many of the newer ones just starting the JAN qualification process—are specifically characterized on Standard Military Drawings (SMDs). Most of our ICs are available in versions that comply with MIL-STD-883C Class B, and many also comply with Class S. We publish a *Military Products Databook* for designers who specify ICs and hybrids for military contracts. The 1990 issue consists of two volumes with data on 343 product families; the 120 entries in the second of those volumes describe qualified products manufactured by our PMI Division. A newsletter, *Analog Briefings®*, provides current information about the status of reliability at ADI.

Our PLUS program makes available standard devices (commercial and industrial grades, plastic or ceramic packaging) for *any* user with demanding application environments, at a small premium. Subjected to stringent screening, similar to MIL-STD-883 test methods, these devices are suffixed "/+" and are available from stock.

PRODUCTS NOT FOUND IN THE SELECTION GUIDES

For maximum usefulness to designers of new equipment, we have limited the contents of selection guides to standard products most likely to be used for the design of new circuits and systems. If the model number of a product you are interested in is not in the Index, turn to page 12–4 at the back of this volume where you will find a list of older products for which data sheets are available upon request. On page 12–5 you will find a guide to substitutions (where possible) for products no longer available.

ICs embodying combinations of functions that you need but cannot find among our standard offerings may be available to meet your specific requirements as custom designs. Consult the section in this book on Application Specific ICs—and/or get in touch with Analog Devices.

PRICES

Accurate, up-to-date prices are an important consideration in making a choice among the many available product families. Since prices are subject to change, current price lists and/or quotations are available upon request from our sales offices and distributors .

A/D Converters – Section 2 2–1

Selection Trees 2–3
Selection Guides 2–7
Orientation 2–14
AD570/571 – 8- and 10-Bit Analog-to-Digital Converters 2–25
AD572 – 12-Bit Successive Approximation Integrated Circuit A/D Converter 2–31
AD573 – 10-Bit A/D Converter 2–33
AD574A – Complete 12-Bit A/D Converter 2–41
AD575 – Complete 10-Bit A/D Converter with Serial Output 2–53
AD578/579 – Very Fast Complete 10- or 12-Bit A/D Converters 2–61
AD670 – Low Cost Signal Conditioning 8-Bit ADC 2–69
AD671 – Monolithic 12-Bit 2 MHz A/D Converter 2–81
AD673 – 8-Bit A/D Converter 2–97
AD674A – Complete 12-Bit A/D Converter 2–105
AD674B/774B – Complete 12-Bit A/D Converter 2–109
AD675 – 16-Bit 100 kSPS Sampling ADC 2–121
AD676 – 16-Bit 100 kSPS Sampling ADC 2–123
AD678 –12-Bit 200 kSPS Complete Sampling ADC 2–137
AD679 – 14-Bit 128 kSPS Complete Sampling ADC 2–149
AD770 – 200 MSPS Wideband 8-Bit A/D Converter 2–161
AD773 – 10-Bit 18 MSPS Monolithic A/D Converter 2–173
AD776 – 16-Bit 100 kSPS Oversampling ADC 2–189
AD779 – 14-Bit 128 kSPS Complete Sampling ADC 2–191
AD1170 – High Resolution Programmable Integrating A/D Converter 2–203
AD1376/1377 – Complete High Speed 16-Bit A/D Converters 2–215
AD1378 – Complete Wide Temperature 16-Bit A/D Converter 2–223
AD1380 – Low Cost 16-Bit Sampling ADC 2–231
AD1382 – 16-Bit 500 kHz Sampling ADC 2–239
AD1385 – 16-Bit 500 kHz Wide Temperature Range Sampling ADC 2–255
AD1671 – Complete 12-Bit 1.25 MSPS Monolithic A/D Converter 2–259
AD1674 – 12-Bit 100 kSPS A/D Converter 2–269
AD1876 – 16-Bit 100 kSPS Sampling ADC 2–283
AD1878 – High Performance Stereo 16-Bit Oversampled ADC 2–295
AD1879 – High Performance Stereo 18-Bit Oversampled ADC 2–297
AD7572 –LC^{2}MOS Complete High Speed 12-Bit ADC 2–299
AD7572A – LC^{2}MOS Complete High Speed 12-Bit ADC 2–303
AD7574 – CMOS µP-Compatible 8-Bit ADC 2–315
AD7575 – LC^{2}MOS 5 µs 8-Bit ADC with Track/Hold 2–323
AD7578 – CMOS 12-Bit Successive Approximation ADC 2–335
AD7579/7580 – LC^{2}MOS 10-Bit Sampling A/D Converters 2–347
AD7581 – CMOS µP-Compatible 8-Bit 8-Channel DAS 2–363
AD7582 – CMOS 12-Bit Successive Approximation ADC 2–371
AD7586 – LC^{2}MOS 12-Bit 1 µs ADC 2–383
AD7672 – LC^{2}MOS High Speed 12-Bit ADC 2–391

***AD7892**	**12**	**140**	**70**	**2.5 V, Ext**	**8/12/Serial, µP**	**2, 3, 6**	**I, M**	**C II 2–663**	**±10 V Input, Single Supply Sampling ADC**
AD1332	**12**	**125**	**125**	**−5 V, Int**	**12, µP**	**1**	**I, M**	**C II 7–17**	**Complete 12-Bit 125 kHz Sampling ADC for Digital Signal Processing, On-Chip FIFO**

[1]X indicates that the internal SHA bandwidth is not specified in kHz.
[2]Ext indicates external reference with the range of voltages listed where applicable. Ext (M) indicates external reference with multiplying capability. Int indicates reference is internal. A voltage value is given if the reference is pinned out.
[3]This column lists the data format for the bus with "µP" indicating microprocessor capability—i.e., for a 13-bit converter 8/12, µP indicates that the data can be formatted for an 8-bit bus or can be in parallel (12 bits) and is microprocessor compatible.
[4]Package Options: 1 = Hermetic DIP, Ceramic or Metal; 2 = Plastic or Epoxy Sealed DIP; 3 = Cerdip; 4 = Ceramic Leadless Chip Carrier; 5 = Plastic Leaded Chip Carrier; 6 = Small Outline "SOIC" Package; 7 = Hermetic Metal Can; 8 = Hermetic Metal Can DIP; 9 = Ceramic Flatpack; 10 = Plastic Quad Flatpack; 11 = Single-In-Line "SIP" Package; 12 = Ceramic Leaded Chip Carrier; 13 = Nonhermetic Ceramic/Glass DIP; 14 = J-Leaded Ceramic Package; 15 = Ceramic Pin Grid Array; 16 = TO-92.
[5]Temperature Ranges: C = Commercial, 0 to +70°C; I = Industrial, −40°C to +85°C (Some older products −25°C to +85°C); M = Military, −55°C to +125°C.
Boldface Type: Product recommended for new design.
*New product since the publication of the most recent Databooks.

[1]X indicates that the internal SHA bandwidth is not specified in kHz.

[2]Ext indicates external reference with the range of voltages listed where applicable. Ext (M) indicates external reference with multiplying capability. Int indicates reference is internal. A voltage value is given if the reference is pinned out.

[3]This column lists the data format for the bus with "µP" indicating microprocessor capability—i.e., for a 13-bit converter 8/12, µP indicates that the data can be formatted for an 8-bit bus or can be in parallel (12 bits) and is microprocessor compatible.

[4]Package Options: 1 = Hermetic DIP, Ceramic or Metal; 2 = Plastic or Epoxy Sealed DIP; 3 = Cerdip; 4 = Ceramic Leadless Chip Carrier; 5 = Plastic Leaded Chip Carrier; 6 = Small Outline "SOIC" Package; 7 = Hermetic Metal Can; 8 = Hermetic Metal Can DIP; 9 = Ceramic Flatpack; 10 = Plastic Quad Flatpack; 11 = Single-in-Line "SIP" Package; 12 = Ceramic Leaded Chip Carrier; 13 = Nonhermetic Ceramic/Glass DIP; 14 = J-Leaded Ceramic Package; 15 = Ceramic Pin Grid Array; 16 = TO-92.

[5]Temperature Ranges: C = Commercial, 0 to +70°C; I = Industrial, −40°C to +85°C (Some older products −25°C to +85°C); M = Military, −55°C to +125°C.

Boldface Type: Product recommended for new design.

*New product since the publication of the most recent Databooks.

[1]Ext indicates external reference with the range of voltages listed where applicable. Ext (M) indicates external reference with multiplying capability. Int indicates reference is internal. A voltage value is given if the reference is pinned out.

[2]This column lists the data format for the bus with "µP" indicating microprocessor capability—i.e., for a 12-bit converter 8/12, µP indicates that the data can be formatted for an 8-bit bus or can be in parallel (12 bits) and is microprocessor compatible.

[3]Package Options: 1 = Hermetic DIP, Ceramic or Metal; 2 = Plastic or Epoxy Sealed DIP; 3 = Cerdip; 4 = Ceramic Leadless Chip Carrier; 5 = Plastic Leaded Chip Carrier; 6 = Small Outline "SOIC" Package; 7 = Hermetic Metal Can; 8 = Hermetic Metal Can DIP; 9 = Ceramic Flatpack; 10 = Plastic Quad Flatpack; 11 = Single-in-Line "SIP" Package; 12 = Ceramic Leaded Chip Carrier; 13 = Nonhermetic Ceramic/Glass DIP; 14 = J-Leaded Ceramic Package; 15 = Ceramic Pin Grid Array; 16 = TO-92.

[4]Temperature Ranges: C = Commercial, 0 to +70°C; I = Industrial, −40°C to +85°C (Some older products −25°C to +85°C); M = Military, −55°C to +125°C.

Boldface Type: Product recommended for new design.

*New product since the publication of the most recent Databooks.

Analog-to-Digital Converters

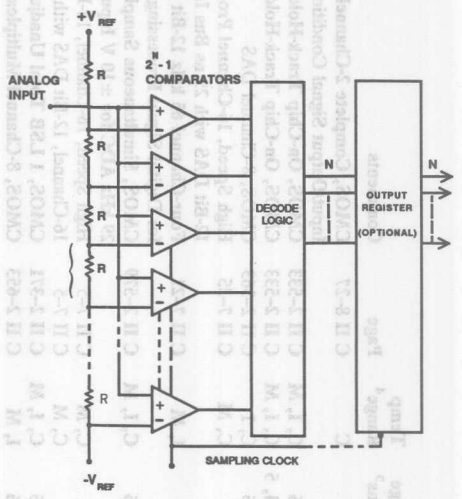
FACTORS IN CHOOSING AN A/D CONVERTER

This section contains technical data and selection guides for *stand-alone general- and special-purpose analog-to-digital converters* (ADCs), including many *sampling* types. Devices and subsystems that perform analog-to-digital conversion functions are also to be found in many other sections of this reference manual; they include ICs (general purpose and application specific), multichip modules, and larger packages:

- V/F and F/V Converters (for low noise, high resolution conversion applications)
- Synchro- and Resolver-to-Digital Converters (for position- and motion-control applications)
- Data Acquisition Subsystems (for applications requiring signal conditioning combined with conversion)
- I/O Ports (for applications requiring both A/D & D/A conversion)
- Bus Interface and Serial I/O Products (subsystems)
- Digital Panel Meters
- ASICs (systems-on-a-chip for custom applications)
- Communications Products (codecs for modems, DSP peripherals, etc.)

The devices in this section include approximately 80 different families of analog-to-digital converters (ADCs) constructed using elements of a few basic architectures. If one were to consider all the variations, there would be hundreds of different types among which to choose. Why so many?

The answer is found in the diversity of real-world applications. Besides the key parameters, *resolution* and *speed*, many other considerations influence the choice of converter for a given application. Among the degrees of freedom are static and dynamic accuracy, digital data interface, control interface and timing, sample-and-hold capability, the analog signal, reference requirements, calibration capability, number of channels, power consumption, environmental requirements, package constraints, and software-related issues.



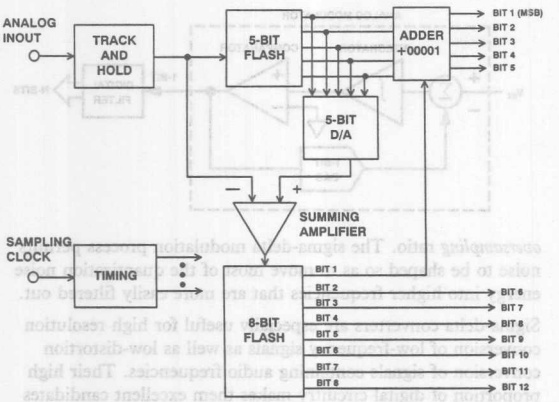
In this section, we discuss the various types of converter architectures that have evolved to deal with these considerations, followed by a glossary that includes definitions of the most-important specifications and many additional terms. Much additional information can be found in books listed in the Technical Publications section, starting on page 12–8, particularly the Analog Devices *High-Speed Design Seminar* (1990) and *Mixed-Signal Design Seminar* (1991) and the classic *Analog-Digital Conversion Handbook* from Prentice Hall (1986); all of these can be purchased from Analog Devices at reasonable cost.

FUNCTIONAL CHARACTERISTICS

Direct Conversion

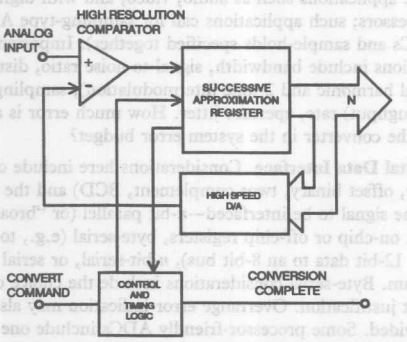
In concept, the simplest—and fastest—A/D converter is one that performs a conversion directly. The basic architectural element of all A/D converters is a 1-bit converter, the comparator. If the input signal, applied to the + input (for example), is greater than a reference, applied to the − input, the output goes high ("1"); if the input signal is less, the output goes low ("0").

A "*flash*"—or direct—converter provides the fastest multibit conversion. The basic n-bit flash converter typically consists of $2^n - 1$ comparators* connected in parallel, with references spaced $V_{FS}/2^n$ (i.e., 1 LSB) apart; if the input signal increases, more comparators go high. The latched comparator outputs are combined by a priority encoder to form parallel n-bit digital words. An example of flash converter is the 10-bit AD9060, which can convert at a rate of 75 megasamples per second.



The space, input capacitance, and power required by large numbers of comparators have historically limited the resolution available with direct conversion. For this reason, most of the converters in use today perform a sequence of partial direct conversions and/or rely on an indirect method involving time integrations.

Partial Conversions in Sequence

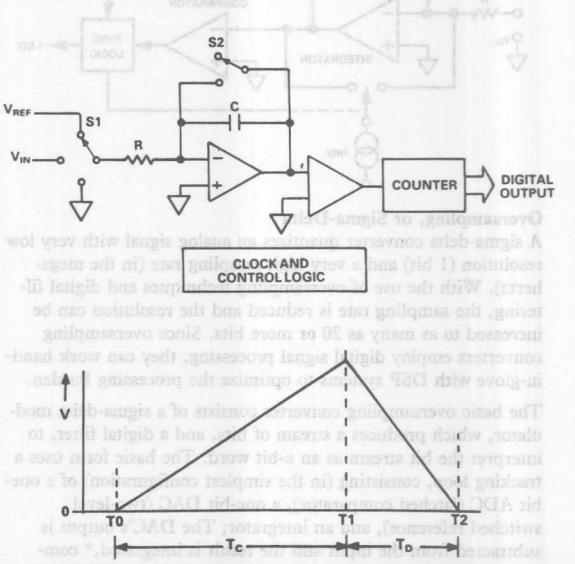


Converters in this class perform several conversions involving one or more bits to arrive at the complete n-bit conversion.

- *Subranging Converters* use two or more steps of lower-resolution flash conversion to convert an analog signal at high speeds with resolutions of up to 14 bits (e.g., the 14-bit, 10 MSPS hybrid AD9014, and the 12-bit, 500 ns monolithic AD671). For example, in performing an n-bit conversion using two steps of subranging, first a coarse m-bit conversion is performed, then the result is converted back to one of 2^m levels—using a D/A converter with at least n-bit accuracy—and compared with the input. The difference is then converted with a k-bit converter (where $k + m \geq n$) and the two outputs are combined. If $k + m > n$, digital correction may be used to eliminate overlap errors.

*An efficient variation of the flash converter, invented at Analog Devices (U.S. Patent 4,928,103) uses one-half as many input comparators.

- *Successive Approximations*. In this popular technique, a single comparator is used to compare the input with the output of an n-bit DAC as a reference, and n single-bit conversions are performed—in a manner similar to weighing an object on a chemist's balance with binary weights. Using a successive-approximations (shift) register (SAR), the MSB of the DAC is asserted and the input is compared with the MSB alone (one-half the DAC's span). The choice (1 or 0) is latched in and—applied to the DAC—fixes the DAC output (at 0 or 1/2).

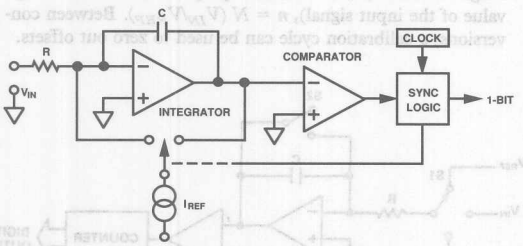


The register is clocked, the second bit is asserted, and the input is now compared with the first result plus the second bit, (0 + 1/4) or (1/2 + 1/4). The result of the second-bit test (1 or 0) is latched in; the DAC's output is either 0, 1/4, 1/2, or 3/4; the third bit is asserted; and the process continues until the LSB has been tried, the DAC output is within 1/2 LSB of the input, and all n bits have been latched into the corresponding states. Successive-approximation converters are widely used because they are capable of speeds approaching 1 MHz and resolutions up to 16 bits and more. A typical example is the industry-standard 12-bit AD574A, plus its variants and successors.

Integrating Converters

Integrating converters have two main sections, a measuring section—that converts the analog information to a time interval or a train of pulses—and a counter or filter to quantify the result as a digital number.

- *Dual-Slope*. Typically, a dual-slope converter consists of an analog integrator with switched inputs, a comparator, and a counter. Starting from an initial value and computing for a fixed interval (number of counts), $N\Delta t$, with the analog input signal applied, the output of the integrator traverses a range proportional to the average value of the analog signal, V_{IN}. At the end of the N counts, a fixed reference voltage of opposite sense to the signal is applied, and the integrator ramps linearly in the opposite direction until the comparator detects that the integrator output has reached the original starting point—after n counts. Since n is proportional to the voltage range traversed (which in turn is proportional to the average value of the input signal), $n = N\,(V_{IN}/V_{REF})$. Between conversions, a calibration cycle can be used to zero out offsets.



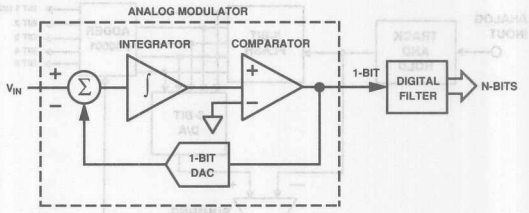
THE INTEGRATOR CHARGES FOR FIXED TIME T_C WITH V_{IN}. THE DISCHARGE TIME WITH A FIXED REFERENCE (= V_{REF}) INPUT IS THEN MEASURED (T_D).

$$\text{RATIO}\,\frac{|V_{IN}|}{|V_{REF}|} = \frac{T_D}{T_C}$$

The inherent −6-dB-per-octave low-pass characteristic of the integrator in dual-slope converters tends to reject high frequency noise; in addition, noise components having periods that are submultiples of the signal-integration interval (N) will integrate to zero. Δt may therefore be chosen to reject noise at power frequency (e.g., 50 or 60 Hz) and its harmonics. Because of the

time required for integration, these types of converters tend to be used for signals having relatively low bandwidths (compared to the types discussed above). They are especially useful where noisy signals are to be converted and relatively infrequent updating is necessary, for example in numeric display of voltage (e.g., digital panel meters).

Charge-Balance. This architecture is used by voltage-to-frequency converters and is similar to architectures used for Σ-Δ types. Employing a free-running integrator in a feedback loop, it continually seeks to null its input by subtracting precisely determined packets of charge when the accumulated charge exceeds a reference value. The number of charge packets per second (or frequency) required to balance a given input is proportional to the input. A counter may be used to convert the serial pulse train to a digital word. The figure shows a synchronous charge-balance voltage-to-frequency converter.



Oversampling, or Sigma-Delta

A sigma-delta converter quantizes an analog signal with very low resolution (1 bit) and a very high sampling rate (in the megahertz). With the use of oversampling techniques and digital filtering, the sampling rate is reduced and the resolution can be increased to as many as 20 or more bits. Since oversampling converters employ digital signal processing, they can work hand-in-glove with DSP systems to optimize the processing burden.

The basic oversampling converter consists of a sigma-delta modulator, which produces a stream of bits, and a digital filter, to interpret the bit stream as an *n*-bit word. The basic form uses a tracking loop, consisting (in the simplest configuration) of a one-bit ADC (latched comparator), a one-bit DAC (two-level switched reference), and an integrator; The DAC's output is subtracted from the input and the result is integrated,* compared to zero, and latched at a megahertz rate; the DAC feeds back a one-bit analog representation of the ADC's output, a serial stream of bits—1s and 0s. The bit stream is filtered digitally to trade speed for resolution.

Because sigma-delta converters latch on a high speed clock pulse, they do not require sample-holds. Since the bit stream is a train of 1s and zeros, there are no missing codes. The digital filtering is essentially another sampling operation; it produces data at a rate less than one-half the fast clock rate but substantially higher than twice the maximum signal bandwidth. The ratio of the output data rate to the input's Nyquist rate is the

oversampling ratio. The sigma-delta modulation process permits noise to be shaped so as to move most of the quantization noise energy into higher frequencies that are more easily filtered out.

Sigma-delta converters are especially useful for high resolution conversion of low-frequency signals as well as low-distortion conversion of signals containing audio frequencies. Their high proportion of digital circuitry makes them excellent candidates for high yield manufacture in IC form.

APPLICATION CONSTRAINTS

The many factors that call for large numbers of different devices are summarized briefly here. Definitions and discussions of terms used will be found in the glossary.

- **Static and Dynamic Accuracy.** Examples of static accuracy specifications, required in many precision low-frequency applications, include differential and integral nonlinearity, missing-code specs, gain error, offset error and drift, as well as conversion time (or rate). Dynamic accuracy is important in ac applications such as audio, video, and with digital signal processors; such applications call for sampling-type ADCs (or ADCs and sample-holds specified together). Important specifications include bandwidth, signal-to-noise ratio, distortion (total harmonic and 2-tone intermodulation), sampling (or throughput) rate, aperture jitter. How much error is allowed for the converter in the system error budget?
- **Digital Data Interface.** Considerations here include code (binary, offset binary, twos complement, BCD) and the format of the signal to be interfaced—*n*-bit parallel (or "broadside"), with on-chip or off-chip registers, byte-serial (e.g., to interface 12-bit data to an 8-bit bus), *n*-bit-serial, or serial bit stream. Byte-serial considerations include the choice of left or right justification. Overrange error indication may also be provided. Some processor-friendly ADCs include one or more words (FIFO) of buffer memory; less-friendly ADCs may rely on interrupts to indicate when conversions have been completed. What logic compatibility is required (TTL, low-voltage CMOS, high voltage CMOS, ECL)?
- **Control Interface and Timing.** These specify modes of chip selection and enabling, starting conversions, status indication (busy, data ready, end of conversion), data format, short cycle, conversion clocking, repetitive (continuous) conversions, sample-hold control, serial clock, synchronization, reset, and "sleep" mode (to minimize dissipation). They may also control analog functions, such as bipolar offset, gain, self-calibration modes, and selection of multiplexer channel.

*The name, sigma-delta, is a consequence of the integral, or summation over time (Σ), applied to the difference (Δ).

- **Sampling Capability**. An ADC requires a low-jitter sample/hold (or track/hold) function to maintain a constant input value during conversion, to establish precisely the instant of time associated with the converted data, and—in consequence—to obtain a train of regularly spaced conversions for digital signal-processing applications. For applications where a sample-hold function is needed, sampling ADCs (SADCs) eliminate the need for an external sample-hold function. Where all other considerations are met, this has the key advantages of compactness, combined tested specifications (usually better than for separate devices), and lower cost. Some sampling converters are ready for another sample well before a multiple-step conversion has been completed; this *pipelining* makes it possible to speed up the conversion rate for multiple conversions; but for an isolated data point one must consider *latency*, the time required for a complete single conversion.
- **The Analog Signal**. Elements of choice include range, whether unipolar or bipolar, and bandwidth. What resolution is desired? Is it single-ended or differential? Is signal conditioning needed (isolation, fixed or programmable gain or attenuation, I-to-V conversion, offsetting, noise filtering, multiplexing)? Is it already sampled? Is the output low enough in dynamic impedance to drive a proposed ADC's input? (If not, a buffer amplifier may be needed.) Is impedance matching necessary to avoid reflections? What sort of ground management will be necessary?
- **Reference Requirements**. What reference range and polarity are needed? Is an internal reference desired, or will a system reference be used? (Or will the converter's internal reference provide the system reference?) Is the converter to be used ratiometrically (because the variable actually converted is the ratio of signal to reference, accuracy can be gained by using for the converter the same reference that provides excitation for an input source, e.g., bridge excitation voltage). What current load must it supply? Is one end grounded, or must its output be differential? Are Kelvin connections necessary? desirable? available? Are the gains and/or the bipolar offset jumpered externally or switched by software.
- **Calibration Capability**. How are the offset and gain trimmed? Are zeroing and/or gain adjustment terminals available? Are trim DACs provided on chip for digital adjustment? Is calibration performed automatically on the device? Periodically or on request?
- **Number of Channels**. Does the application call for more than one input? Is multiplexing to be provided on- or off-chip? Is more than one A/D conversion at a time needed simultaneously in the same device? Is a multiple sample-hold needed for simultaneous sampling of input channels? Can conversion of a single channel be speeded up by "ping-ponging" pairs of sampling converters? Does a fast converter have a pair of alternately updated output registers so that its output can be distributed to two slow memory channels?
- **Clock**. Considerations include: speed range, drive required, edge rate, allowable overshoot, internal/external system clock, duty cycle, rising/falling-edge reference.
- **Power Supply**. What supply voltage levels are available? Is the supply a switching or a linear type? What are the power supply's regulation and noise characteristics? What sort of bypassing will be needed? Is there a limitation on available current drain or power dissipation? What are the supply's power-up characteristics? Is operation continuous or intermittent? Is a reference voltage to be derived from the power supply? Where is the supply located physically in relation to the converter and analog signals? Are electrical or magnetic fields associated with the supply likely to cause problems? Are remote devices powered centrally or locally? What is the best grounding scheme? Is isolation desirable?
- **Environmental Requirements**. What is the specified operating temperature range: 0°C to +70°C (commercial), −25°C to +85°C (industrial), −40°C to +85°C (extended industrial), or −55°C to +125°C (military)? What other environmental aspects are of importance (humidity, barometric pressure, dust, moisture, shock, vibration, ionizing radiation)? What behavior is expected in worst-case environmental conditions (survival, reliable operation, performance within specifications)? Is the environment electrically noisy? What is the character of the noise (amplitude, frequency, waveshape)?
- **Package Constraints**. What level of physical protection is required (chip, multichip reel, plastic package, hermetic package)? What kind of package and interconnections does your customer specify? What is the assembly method (automated, surface-mount, chip-and-wire, manually board-mounted)? How much space is available? Is a completely self-contained device desirable? What terminals or functions must be accessible?
- **Software- and Control-Related Issues**. Is conversion to occur at a regular rate or on the occurrence of an event? How much latency is permissible? How much time is available for conversion? For bus access? Must the conversion results be used immediately? If not, must buffer capacity be available to store more than one result? Must a new conversion start as soon as the last one ended? Is glue logic undesirable?

SPECIFICATIONS AND TERMS

Definitions of performance specifications and other frequently used terms will be found below in alphabetical order. Since they tend to be broad and generally applicable, specific data sheets and application notes should be consulted for details as they apply to specific products and applications.

Accuracy, Absolute

The error of an A/D converter at a given output code is the difference between the theoretical and the actual analog input voltages required to produce that code. Since the code can be produced by any analog voltage in a finite band (*see* Quantizing uncertainty), the "input required to produce that code" is defined as the midpoint of the band of inputs that will produce the code. For example, if 5 volts (±1.2 mV) will theoretically produce a 12-bit half-scale code of 100000000000, then a converter for which any voltage from 4.997 V to 4.999 V will produce that code will have an absolute error of (4.997 + 4.999)/2 − 5 volts = −2 mV.

Absolute error comprises gain error, zero error and nonlinearity, together with noise. Absolute-accuracy measurements should be made under a set of standard conditions with sources and meters traceable to an internationally accepted standard.

Accuracy, Relative
Relative accuracy error, expressed in percent, parts per million, or fractions of an LSB (full-scale range/2^n), is the deviation of the analog value at any code, (relative to the full analog range of the device transfer characteristic) from its theoretical value (relative to the same range) after the full-scale range (FSR) has been calibrated.

Since the discrete points on the theoretical transfer characteristic lie on a straight line, this deviation can also be interpreted as a measure of *nonlinearity*.

The "discrete points" of an A/D transfer characteristic are the midpoints of the quantization bands at each code (*see* Accuracy, absolute). However, since transitions between codes are easier to find than the midpoints, this characteristic is often defined in terms of an adjacent transition, usually the low-side transition.

Aliasing
A signal within a bandwidth, f_A, must be sampled at a rate, $f_S > 2\,f_A$ in order to avoid loss of information. If the number of samples of a signal, f, is inadequate, i.e., $f_S < 2\,f$, a phenomenon called aliasing, inherent in the spectrum of the sampled signal, will cause a frequency equal to $f_S - f$, called an "alias" to appear in the signal band (of frequencies below $f_S/2$). For example, if f_S = 4 kHz and f = 3 kHz, a 1 kHz alias will appear. Note also that, for a 1 kHz signal (which is *within* the band, $f_S/2$), the alias will be at 3 kHz, *outside* the band. Since noise is also aliased, it is essential to provide low-pass filtering prior to the sampling stage to prevent high frequency noise on the signal line from being aliased into the signal range.

Analog-to-Digital Converter (ADC)
An analog-to-digital converter quantizes an analog input voltage (i.e., measures and assigns it to one of 2^n equal ranges, or *quanta*, within the expected span) and interprets the quantum as a digital number.

Aperture Jitter
Aperture jitter is the sample-to-sample variation in the space in time between the effective points at which the samples are actually taken. It is often due to phase jitter on the input sine wave or unwanted phase-modulation of the sampling clock by sources such as random noise, power line noise, or digital noise stemming from poor layout, bypassing, or grounding. The resulting error can be expressed in terms of an rms time jitter, which produces a corresponding rms voltage error, decreasing the overall ADC signal-to-noise ratio.

When a sample-hold is used ahead of a nonsampling A/D converter (typically successive-approximation and flash), the timing uncertainty of the conversion process is reduced by the ratio of aperture jitter to the conversion time. Expressed another way, the maximum frequency that can be handled with less than 1 LSB error due to timing is $2^{-n}/(\pi\tau_a)$, instead of $2^{-n}/(\pi\tau_c)$, where τ_a is the aperture uncertainty and τ_c is the conversion time.

Aperture Time (Delay)
Aperture time (sometimes called aperture *delay* time—although it may be either a delay or an advance) is a measure of the interval between the leading edge of the sampling clock and the instant at which the sample-hold or sampling ADC actually takes the sample. The variation or tolerance placed on this parameter from part to part is important in simultaneous sampling applications or other applications where ADCs are required to track each other when processing dynamic signals. Timing can be advanced or delayed to improve accuracy, but precision is ultimately limited by *aperture jitter*.

Bandwidth, Full-Linear
The full-linear bandwidth is the input frequency at which the slew-rate limit of the sample-hold amplifier (SHA) is reached. Up to this point, the amplitude of the reconstructed fundamental will have been attenuated by less than 0.1 dB. Beyond this frequency, distortion of the sampled input signal increases significantly.

Bandwidth, Full-Power (FPBW)
The full-power bandwidth is that input frequency at which the amplitude of the reconstructed fundamental (using FFTs) is reduced by 3 dB for a full-scale input. In order to be meaningful, the FPBW must be examined in conjunction with the signal-to-noise ratio (SNR), effective number of bits (ENOB), and harmonic distortion in order to ascertain the true dynamic performance of the ADC at the FPBW frequency.

Binary Coding
The digital output of an ADC is considered binary-coded when outputs start at all-zeros for a zero-scale (unipolar) analog input, increasing to all-ones for FSR ($1 - 2^{-n}$), in binary sequence. For a bipolar analog range, all-zeros starts at negative full-scale, increasing in binary sequence to FSR ($1 - 2^{-n+1}$) for all ones; this coding is called *offset binary*, which is easy for converters but not useful for computers; however, it is easily converted to *twos complement* by complementing the MSB.

Bipolar Mode
A configuration that an A/D converter uses to handle signal spans containing both positive and negative signals. Usually it means offsetting half-scale to become analog zero, and either accepting the resulting offset binary code or changing it to twos complement by complementing the most-significant bit (*see* Binary Coding).

Bipolar Negative Full-Scale Error
In bipolar converters, for the first step of code (from 0000 . . . 00 to 0000 . . . 01 in offset binary, or 1000 . . . 00 to 1000 . . . 01 in twos complement), the ideal transition occurs at 1/2 LSB above $-V_{REF}$. Bipolar negative-full-scale error is the deviation of the first code transition from the ideal when operating in the bipolar mode.

Bipolar Zero Error (Offset) and Drift
In the bipolar mode, this is the deviation of the midscale transition (011 . . . 111 to 100 . . . 000 in offset binary, 111 . . . 111 to 000 . . . 000 in twos complement) from the ideal (A_{GND} – 0.5 LSB).

Bus
A parallel path of binary information signals—usually 8, 16, or 32 bits wide. Three common types of information usually found on buses are data, addresses, and control signals. 3-state output switches (inactive, high, and low) permit many sources—such as ADCs—to be connected to a bus, while only one is active at any time.

Byte
A byte is a binary digital word, usually 8 bits wide. A byte is often part of a longer word that must be placed on an 8-bit bus in two stages. The byte containing the MSB is called the *high byte*; that containing the LSB is called the *low byte*. A four-bit byte is called a *nybble*.

Byte, High
When a 12- or 16-bit word is placed on an 8-bit bus in two stages, the high byte contains the 4- or 8 most-significant bits. If 8, a 12-bit word is said to be left-justified; if 4 (plus filled-in leading sign bits), the word is said to be right justified.

Byte, Low
When a 12- or 16-bit word is placed on an 8-bit bus in two stages, the low byte contains the 4- or 8 least-significant bits. If 8, a 12-bit word is said to be right justified; if 4 (plus trailing zeros), the word is said to be left-justified.

Capacitance, Input (C_{IN})
The capacitance measured between the analog input and all supply pins (including grounds) of an A/D converter. Input capacitance often varies with input voltage, so it should be measured at worst-case input voltage. This parameter is important at high input frequencies because an amplifier or track-and-hold must drive it without introducing unacceptable levels of distortion.

Chip Select ($\overline{CS}$)
A logic input signal activating data or control information transfer between the ADC and the digital circuitry. This signal is usually active-low, as designated by the overbar. $\overline{CS}$ is used in conjunction with additional qualifying logic signals to determine the exact activities to take place.

Clock (CLK)
The operation of many common A/D conversion processes requires a clock to order events in the process. A system clock is also present to time the interfacing between the converter and the system. Operations may depend on clock levels or clock edges, either ascending or descending.

Code, Missing
In practice, the 2^n–2 inner codes (excluding zero and full scale) are always wider or narrower than the ideal 1 LSB, especially in flash, subranging, and successive-approximation converters. If code-width errors (*see* Nonlinearity, Differential) exceed 1 LSB, one or more codes may have zero width; as the input increases, the output will jump between the adjacent codes, e.g., from 11 . . . 011 to 11 . . . 101, skipping 11 . . . 010. A specification that guarantees no missing codes requires that every code combination appear in a monotonically increasing sequence as the analog input level is increased.

Code Repetition
The ability of the ADC to continuously provide the same digital output for a stable analog input voltage in the middle of a code.

Code Width and Uncertainty
Code width is the amount of input voltage change between output code transitions, expressed in LSBs of full scale ($FSR/2^n$). The ideal code width is 1 LSB. Since transition voltage is sensitive to noise and jitter, there is always a degree of uncertainty associated with code-width measurements.

Coding
This term refers to the code and format employed to express an ADC's digital output data. Codes include binary, binary-coded decimal (BCD), offset binary, twos complement, and complementary (*negative-true*) versions of these codes. The codes may be expressed in parallel, byte-serial, and bit-serial formats. Some converters, (e.g., V/Fs) have *uncoded* (i.e., bit-stream) outputs.

Command Register
An internal register of the ADC that can be programmed by the user to select various modes of operation; examples of selection choices include unipolar or bipolar conversion, range, data output format.

Common-Mode Rejection
The ability of a device to reject the effect of voltage applied to both input terminals simultaneously—often through variation of a ground level—is specified as a *common-mode rejection ratio* (CMRR, or in logarithmic form, CMR = 20 log CMRR). CMRR is the ratio of gain for the differential, or *normal-mode*, signal to the gain for the common-mode signal.

Conformance, Straight Line
This term describes how closely the ADC transfer characteristic conforms to a reference straight line. Nonconformance can be described in terms of integral nonlinearity (the difference between the actual code centers and a straight line), or dynamically in terms of waveform distortion. For many applications, this property is far more important than calibration errors and drifts.

Control Lines
Digital input/output pins that activate or monitor and control ADC operation. Examples include chip select, low byte, high byte, start convert, end of conversion, conversion complete, busy, read, etc.

Conversion Complete (CC)
This digital output signal indicates the end of conversions. When this signal is in the opposite state, the ADC is considered to be "busy." Also called end of conversion, or EOC.

Conversion Time (t_C) and Conversion Rate
The time required for a complete measurement by an ADC is called *conversion time*. For most converters (assuming no significant additional delays), this is the same as the inverse of *conversion rate*. For simple sampling ADCs, however, the conversion rate is the inverse of the conversion-time-plus-the-sample-hold's acquisition-time. However, in some high speed sampling converters, because of pipelining, new conversions are initiated before a prior conversion has been completed. Once a train of conversions has been initiated, as in signal-processing applications, the conversion rate can be much faster than the conversion time would imply.

Cycle Time
The time required for the converter clock to finish a complete conversion cycle and be ready to start the next cycle. This can be longer than the conversion time because of a cycle required to reset the successive-approximation register or several cycles longer to perform a calibration. Sometimes known as *latency*.

Delta-Sigma, *see* Sigma-Delta

Differential Nonlinearity (DNL), *see* Nonlinearity

Distortion, (Total) Harmonic
THD is usually measured as the ratio of the rms sum of the next five harmonic components to the rms value of a full-scale fundamental input signal and is expressed as a percentage or in decibels:

$$THD = 10 \log [(V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2)/V_1^2].$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5, and V_6 are the rms amplitudes of the second through the sixth harmonic. The THD can be derived from the measured FFT plot of the device's output spectrum. For input signals or harmonics that are above the Nyquist frequency, the aliased component is used.

Distortion, Intermodulation (IMD)
With inputs consisting of sine waves at two frequencies, f_A and f_B, any device with nonlinearities will create distortion products, of order $(m+n)$, at sum and difference frequencies of $mf_A \pm nf_B$, where $m,n = 0, 1, 2, 3 \ldots$. Intermodulation terms are those for which m or n is not equal to zero. For example, the second-order terms are $(f_A + f_B)$ and $(f_A - f_B)$, and the third-order terms are $(2f_A + f_B)$, $(2f_A - f_B)$, $(f_A + 2f_B)$, and $(f_A - 2f_B)$.

The IMD products are expressed as the decibel ratio of the rms sum of the distortion terms to the rms sum of the measured input signals.

Drift, Temperature
The temperature drifts for full-scale (or *gain*) error, unipolar offset, and bipolar offset specify the maximum change from the initial (25°C) value to the value at T_{MIN} or T_{MAX}.

Dual-Slope Conversion
A form of integrating conversion. See the FUNCTIONAL CHARACTERISTICS section.

Effective Number of Bits
For a sine wave, *signal-to-noise ratio* (SNR) can be expressed in terms of the number of bits. Rewriting the SNR formula, it is possible to get a measure of performance expressed as N, the *effective number of bits* (ENOB).

$$N = (\text{SNR} - 1.76)/6.02$$

Thus, effective number of bits for a device for sine wave inputs at a given input frequency can be calculated directly from its measured SNR.

End of Conversion (EOC)
This digital output signal flags the conversion complete and data-ready condition of an A/D converter.

Feedthrough
Undesirable signal coupling around switches of other devices that are supposed to be turned off or provide isolation, e.g., *feedthrough error* in a multiplexer. It is variously specified in percent, ppm, fractions of 1 LSB, or fractions of 1 volt, with a given set of inputs at a specified frequency.

FIFO (First-In, First-Out Memory)
This is best defined by an example. The AD7878 12-bit sampling ADC, designed to interface with signal processors, has eight words of first-in, first-out (FIFO) memory on-chip. This permits up to 8 data samples to be acquired and stored before the processor is required to read; the benefit is that the software overhead associated with servicing processor interrupts is greatly reduced. The 8 words that were stored can then be read out of the FIFO at maximum processor speed.

"Flash" Converter
A converter providing direct (hence the most rapid) conversion. See the FUNCTIONAL CHARACTERISTICS section.

Frequency-Domain Testing
In one approach, a device is tested dynamically using a sine-wave input and a 2,048-point fast Fourier transform (FFT) to analyze the resulting output. Coherent sampling is used, wherein the ADC sampling frequency and the analog input frequency are related to each other by a ratio of integers. This ensures that an integral multiple of input cycles is captured, allowing direct FFT processing without windowing or digital filtering, which could mask some of the dynamic characteristics of the device. In addition, the frequencies are chosen to be "relatively prime" (no common factors) to maximize the number of different ADC codes that are present in a sample sequence. The result, called prime coherent sampling, is a highly accurate and repeatable measure of the actual frequency-domain response of the converter.

Full-Scale Calibration Range
For self-calibrating Σ-Δ converters in the system calibration mode, the range of voltages the device can accept and still calibrate full-scale accurately.

Full-Scale Error, *see also* Gain Error
The last transition (from 111 . . . 10 to 111 . . . 11) should occur for an analog magnitude 1 1/2 LSB (i.e., 1.5 FSR/2^n) below the nominal full scale. The full-scale error is the deviation of the actual level of the last transition from the ideal level at 25°C without adjusting the offset. The full-scale error can be adjusted to zero.

Full-Scale Range (Span)
The difference between the maximum and minimum analog values for input to an A/D converter.

Gain Drift, *see* Drift

Gain Error
The last transition should occur at an analog value 1 1/2 LSB below the nominal full scale. The first transition is 1/2 LSB above the low end of the scale (zero in unipolar converters, −FS in bipolar converters). The gain error is the deviation of the actual difference between the first and last code transitions from the ideal difference between the first and last code transitions. This error can be adjusted.

Half-Step Offset (Low-Side Transition)
In designing an ADC, since comparisons establish transition points, a half-step offset is necessary to center the analog input voltages halfway between the output code transition points. For example, the successive-approximation converter architecture inherently has a 1 LSB transition voltage (instead of 1/2 LSB) for the first code change if a half-step offset is not inserted.

Impedance, Input
The dynamic load presented by a converter to its input source. In unbuffered successive-approximation converters employing current-summing at the comparator input, the presence of current pulses at the converter's clock frequency mandates that the converter be driven from a low impedance (at the clock frequency) in order to maintain an accurate voltage input.

Input Range (Span)
See Full-Scale Range. See also individual data sheets, especially for devices that provide self-calibration.

Integral Nonlinearity, *see* Nonlinearity

Least-Significant Bit (LSB)
In a digital word, the binary digit with the smallest numerical weighting—or its voltage equivalent. Normally, one LSB is equal to the full-scale range divided by 2^n, where n is the number of bits provided by the converter.

Left-Justified Data
When a 12-bit word is placed on an 8-bit bus in two stages, the high byte contains the 4- or 8 most-significant bits. If 8, the word is said to be left justified; if 4 (plus filled-in leading sign bits), the word is said to be right justified.

Linearity Error, *see* Nonlinearity

Major Transition
The digital output code change at one-half the full span, from 011 . . . 111 to 100 . . . 000.

Missing Codes, *see* Code

Most-Significant Bit
The binary digit with the largest numerical weighting. Normally, the MSB of a digital word has a weighting of 1/2 the full-scale range. In bipolar-input converters, the MSB is also used as a sign bit (representing the upper or lower half of the full-scale range). If placed on a right justified bus wider than the data word, all bits to the left of the MSB should be filled with the same bit.

Noise, Quantization
As the input to an A/D converter increases smoothly, the output moves up in a series of steps. When the analog input is summed with an ideal DAC reconstruction, these steps produce an error waveform shaped like an irregular sawtooth as each bit transition is crossed. This waveform can be considered as a type of white noise. In sigma-delta converter design, the quantization-noise spectrum is shaped so as to move most of its energy out of the baseband, a key to the low noise and high resolution available in these converters.

Noise, Transition
As repeated conversions are made in the vicinity of a transition, the transition will be found to occur at somewhat differing values of input. Transition noise is the rms value of the variation in the transition region.

Nonlinearity, AC (Histogram Method)
A full-scale sine wave is applied to the ADC and a large number of samples are taken (several million for a 12-bit converter, to achieve statistically satisfactory results). The number of occurrences of each code is recorded on a histogram plot. The data is normalized by comparison with the U-shaped ideal probability density distribution of a sine wave. From it, DNL can be plotted, and integral nonlinearity can be determined by compiling a cumulative histogram, in which the bin widths are the transition levels. (An example of the results can be found in the AD7870 technical data.)

Nonlinearity, Differential (DNL)
In an ideal ADC, code transitions are 1 LSB apart. Differential nonlinearity is the maximum deviation, expressed in LSBs, from this ideal value. It is often specified in terms of the maximum number of bits for which no missing codes (NMC) are guaranteed.

Nonlinearity, Integral (INL)
The ideal transfer function for an ADC is a straight line drawn between "zero" and "full scale." The point used as "zero" occurs 1/2 LSB before the first code transition. "Full scale" is defined as a level 1 1/2 LSB beyond the last code transition. Integral nonlinearity is the worst-case deviation of a code from the straight line. The deviation of each code is measured from the middle of that code. In some cases, integral nonlinearity is defined with respect to a best-fit straight line, which is typically calculated using the least-squares method.

Nyquist Frequency, Sampling Rate
According to the sampling theorem, a signal within a bandwidth, f_A, must be sampled at a rate, $f_S > 2\,f_A$ in order to avoid loss of information (*see* Aliasing). The "Nyquist (input) frequency" of a converter sampling at f_S is $f_S/2$; alternatively, the "Nyquist (sampling) rate" is $2\,f_A$.

Offset Binary Code
A digital binary code used to represent bipolar analog voltages. Negative full-scale voltage is assigned all-zeros (000 . . . 00), zero voltage is at MSB high—all other bits zero (100 . . . 00), and positive "full-scale" (from a transition 1 1/2 LSB below full-scale) is assigned all-ones (111 . . . 11). The more useful twos-complement code is similar to offset binary, except that the MSB is complemented.

Offset, Bipolar (also Bipolar Zero Error)
In the bipolar mode the major carry transition (011111111111 to 100000000000) should occur for an analog value 1/2 LSB below analog common. The bipolar offset error specifies the maximum deviation of the actual transition point at 25°C. This offset is usually adjustable. The bipolar offset error and temperature coefficient respectively specify the initial deviation and maximum change in the error over temperature.

Offset Calibration Range
For self-calibrating Σ-Δ converters in the system calibration mode, this is the range of voltages the device can accept and still calibrate offset accurately.

Offset, Unipolar
The first transition should occur at a level 1/2 LSB above analog common. Unipolar offset is defined as the deviation of the actual transition from that point at 25°C. This offset can be adjusted.

The *unipolar offset temperature coefficient* specifies the maximum change of the transition point over temperature, with or without external adjustments.

Overrange
When analog input voltages exceed the input range, an overrange condition is in effect. Normally, the digital output code stays at all-ones for positive overrange and all-zeros for negative overrange, with binary coding. Some converters have a digital output flag to signal overrange.

Overrange, Negative Full-Scale
In Σ-Δ converters, negative full-scale overrange is the amount of overhead available to handle input voltages below $-V_{REF}$ (for example, noise peaks or excess voltages due to system gain errors in system calibration routines) without introducing errors due to overloading the analog modulator of Σ-Δ converters or overflowing the digital filter. Note that the analog input will accept negative voltage peaks, even in the unipolar mode.

Overrange, Positive Full-Scale
In Σ-Δ converters, positive full-scale overrange is the amount of overhead available to handle input voltages greater than $+V_{REF}$ (for example, noise peaks or excess voltages due to system gain errors in system calibration routines) without introducing errors due to overloading the analog modulator or overflowing the digital filter of Σ-Δ converters.

Oversampling
Sampling at a rate greater than Nyquist is *oversampling*. If the degree of oversampling is substantial, the noise-filtering problem is ameliorated. Oversampling is the key to the advantages of sigma-delta conversion.

Overvoltage Recovery
Overvoltage recovery time is defined as that amount of time required for the ADC to achieve a specified accuracy after an overvoltage (usually 50% greater than full-scale range), measured from the time the overvoltage signal reenters the converter's range. The ADC should act as an ideal limiter for out-of-range signals, producing a positive or negative full-scale code during the overvoltage condition. Some converters provide over- and underrange flags to allow gain-adjustment circuits to be activated.

Peak Spurious (Peak Harmonic Component)
In the FFT spectrum of a converter output for a given sinusoidal input signal, the peak "spur" is the largest individual spectral component, excluding the input signal and dc. Its magnitude is expressed in dB relative to the rms value of a full-scale input signal. The dB difference in amplitude between it and the signal is the *spurious-free dynamic range* (SFDR).

Pipelining
A pipelined converter is a multistage converter which is capable of accepting a new signal before it has completed the conversion of one or more previous ones. A new signal arrives while others are still "in the pipeline." This is a technique used where a fast conversion rate is highly desirable and the latency of individual conversions is relatively unimportant.

Power Supply Rejection, Sensitivity
For many converters, variations in power supply will affect the scale factor, but not the converter's linearity. Power supply rejection is the maximum change in the full-scale transition point due to a change in power supply voltage from the nominal value.

Quantizing Uncertainty (Error)
The analog continuum is partitioned into 2^n discrete ranges for n-bit conversion. All analog values within a given range are represented by the same digital code, which is assigned to the nominal midrange value. There is, therefore, an inherent quantization uncertainty of ±1/2 LSB, in addition to the actual conversion errors. In integrating converters, this "error" is often expressed as "±1 count."

R-2R Ladder
A resistor network providing the basic binary-current division used in many successive-approximation A/D converters.

Ratiometric Converter
The output of an A/D converter is a digital number proportional to the ratio of (some measure of) the input to a reference. Many requirements for conversions call for an absolute measurement, i.e., against a fixed reference. In some cases, where the measurement is affected by a changing reference voltage (e.g., the voltage applied to a bridge), it is advantageous to use that same reference as the reference for the conversion, to eliminate the effect of variation.

Reference
The reference voltage establishes an A/D conversion system's accuracy at full scale. At other voltages, the integral nonlinearity and reference determine absolute accuracy. References may be furnished either externally or internally.

Resolution
Resolution of an ADC is the number of states (2^n) that the analog input voltage is resolved—or divided—into, where n is equal to the number of bits.

Right Justified Data
When a 12-bit word is placed on an 8-bit bus in two stages, the high byte contains the 4- or 8 most-significant bits. If 8, the word is said to be left-justified; if 4 (plus filled-in leading sign bits), the word is said to be right justified.

Sampling A/D Converter
A sampling A/D converter includes a sample-hold which acquires the input value at a given instant and holds it throughout the conversion (or until the converter is ready for the next data point). (*See* Aperture Time.)

Sampling Frequency
The rate at which an ADC can continuously convert analog inputs into digital outputs. In successive-approximation converters, clock frequency and data-transfer overhead determine the sampling frequency.

Serial Output
A bit-serial output consists of a series of bits clocked out on a single line. There must be a means of identifying the beginning and end of words; this can be furnished via an additional clock line, by using synchronized clocks, and/or by providing a consistent identifying signature for the beginning of a word. *Byte serial* consists of a series of bytes transmitted in sequence on a bus (*see* Byte).

Settling Time, *see also* Transient Response
Settling time is a function of the sample-hold's (SHA) ability to track fast-slewing signals. This is specified as the maximum time required in track mode after a full-scale step input to guarantee rated conversion accuracy.

Short Cycling
An n-bit successive-approximation converter takes at least n clock cycles to complete a conversion. Some converters have the capability of stopping the conversion at an arbitrary point, thus shortening the cycle. Speeding up the conversion by such an approach is useful for maximizing information transfer when the full n bit accuracy or resolution is not needed for a given conversion.

Sigma-Delta Converter
An A/D converter that uses a one-bit or other low-resolution quantizer and very high oversampling rate, combined with a one-bit or low-resolution DAC in a feedback loop. The digital quantizer output is then followed by a low-pass digital filter to remove the noise and output an n-bit digital representation of the input signal.

Signal-to-Noise and Distortion (S/N+D) Ratio
S/(N+D) is the logarithmic expression (decibels) of the ratio of the rms value of the measured input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc. This is actually the generally accepted definition for signal-to-noise ratio (SNR); in this case, the "+D" is intended to emphasize the inclusion of harmonic distortion for audio applications.

Signal-to-Noise Ratio (SNR)
SNR is the measured signal-to-noise ratio at the output of an ADC. The signal is the rms magnitude of the fundamental. Noise is the RMS sum of all the nonfundamental signals up to half the sampling frequency ($f_{SAMPLE}/2$) excluding DC. SNR is dependent on the number of levels used in the quantization process; the more levels, the smaller the quantization noise. The theoretical signal-to-noise ratio for a sine wave input is given by:

$$\text{SNR} = (6.02\ N + 1.76)\ \text{dB}$$

where N is the number of bits. Thus, for an ideal 14-bit converter, SNR $\approx$ 86 dB.

Slew Rate
Slew rate is the maximum rate of change allowed at the input such that the a digitized recreation of the output will track the input without increased error.

Span
The full-scale analog input range. Some ADCs have resistor- or software-selectable analog input ranges.

Spurious-Free Dynamic Range (SFDR)
The difference, in dB (log scale) between the rms amplitude of the input signal and the peak spurious signal (*see* Peak Spurious).

Status Register
A register indicating current status of the analog-to-digital conversion by means of a Busy or Conversion Complete signal.

Subranging
High-resolution fast conversion using flash converters to perform partial conversions. See the FUNCTIONAL CHARACTERISTICS section.

Successive Approximation Conversion
A popular conversion method in which an n-bit conversion is performed by n successively finer approximations. See the FUNCTIONAL CHARACTERISTICS section.

Successive Approximation Register (SAR)
A digital circuit that controls the operation of a successive-approximation ADC and accumulates the digital output word in its register.

Temperature Coefficients
The temperature coefficients for unipolar offset, bipolar zero, and gain error specify the maximum change from the initial (+25°C) value to the value at T_{MIN} or T_{MAX}.

Three-State (Output Buffer), *see* Bus

Transient Response
The transient response (or settling time) of an ADC is the time required for the ADC to settle to rated accuracy after the application of a full-scale step input.

Transition, *see* Accuracy, Relative

Transition, Major; *see* Major Transition

Undersampling
Sampling at a rate below Nyquist. Ordinarily this results in loss of information. However, the aliasing it produces can be used to translate the sidebands of a high frequency carrier down to a lower frequency for detection and demodulation, provided that the ADC has sufficient analog bandwidth.

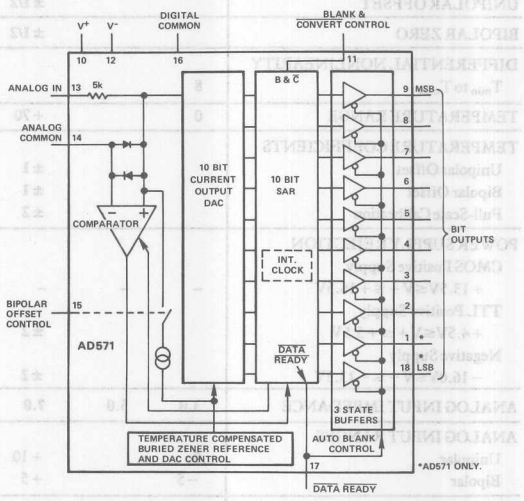
Unipolar Mode
Operation of an ADC with zero-to-full-scale voltage inputs of one polarity only.

Zero- and Gain Adjustment Principles
The zero adjustment of a unipolar ADC is set so that the transition from all-bits-off to LSB-on occurs at $1/2 \times 2^{-n}$ of nominal full scale. The gain is set for the final transition to all-bits-on to occur at FS $(1 - [3/2 \times 2^{-n}])$.

The "zero" of an offset-binary bipolar ADC is set so that the first transition occurs at $-\text{FS}\ (1 - 2^{-n})$ and the last transition at FS $(1 - [3 \times 2^{-n}])$. The data sheet instructions should be followed.

Zero-Code Error
The difference between the ideal 1/2-LSB offset at zero of an ADC and the actual value of input required to produce the first transition.

Zero Drift
The change with temperature of analog zero for an ADC operating in the unipolar mode. It is generally expressed in ppm of FS/°C, or LSBs.



8- and 10-Bit Analog-to-Digital Converters

AD570/AD571*

FEATURES

Complete A/D Converters with Reference and Clock
AD570: 8 Bit
AD571: 10 Bit
Fast Successive Approximation Conversion – 25μs
No Missing Codes Over Temperature
Digital Multiplexing – 3 State Outputs
18-Pin Ceramic DIP
Low Cost Monolithic Construction
MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTIONS

The AD570/AD571 are successive approximation A/D converters consisting of a DAC, voltage reference, clock, comparator, successive approximation register and output buffers – all fabricated on a single chip. No external components are required to perform full accuracy conversions in 25μs.

The AD570/AD571 incorporate advanced integrated circuit design and processing technologies. They employ I^2L (integrated logic) processing in the fabrication of the SAR function. Laser trimming of the high stability SiCr thin-film resistor ladder network insures high accuracy, which is maintained with a temperature compensated, subsurface Zener reference.

Operating on supplies of +5V to +15V and −15V, the AD570/AD571 will accept analog inputs of 0 to +10V, unipolar or ±5V bipolar, externally selectable. As the BLANK and $\overline{\text{CONVERT}}$ input is driven low, the three-state outputs will be open and a conversion will commence. Upon completion of the conversion, the $\overline{\text{DATA READY}}$ line will go low and the data will appear at the output. Pulling the BLANK and $\overline{\text{CONVERT}}$ high blanks the outputs and readies the device for the next conversion.

The devices are available in two versions: the "J" and "K" specified for the 0 to +70°C temperature range. The "S" guarantees the specified accuracy and no missing codes from −55°C to +125°C.

PRODUCT HIGHLIGHTS

1. The AD571 is a complete 10-bit A/D converter. The AD570 is an 8-bit version which employs the same architecture. No external components are required to perform a conversion.
2. The AD570/AD571 are single chip devices employing advanced IC processing techniques. Thus, the user has at his disposal a truly precision component with the reliability and low cost inherent in monolithic construction.
3. The converters accept either unipolar (0 to +10V) or bipolar (−5V to +5V) analog inputs by simply grounding or opening a single pin.
4. Each device offers the specified accuracy with no missing codes over its entire operating temperature range.
5. Operation is guaranteed with −15V and +5V to +15V supplies. The devices will also operate with a −12V supply.
6. The AD570 and AD571 are available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current /883B data sheet for detailed specifications.

*Covered by Patent Nos. 3,940,760; 4,213,806; 4,136,349.

AD570/AD571—SPECIFICATIONS

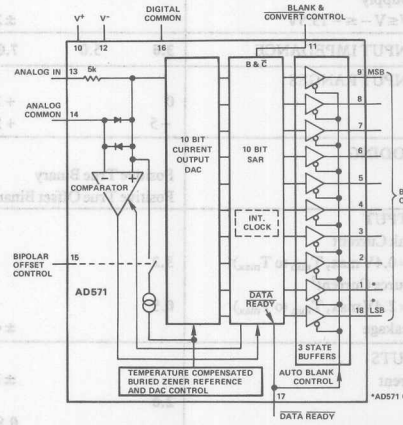
CHIP BONDING DIAGRAM

CIRCUIT DESCRIPTION

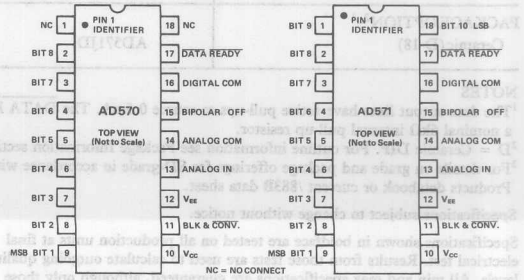


The AD571 is a complete 10-bit A/D converter which requires no external components to provide the complete successive approximation analog-to-digital conversion function. The AD570 is an 8-bit version. A functional block diagram of the AD570/AD571 is shown below. Upon receipt of the CONVERT command, the internal 10-bit (AD571) current output DAC is sequenced by the I^2L successive approximation register (SAR) from its most-significant bit (MSB) to least-significiant bit (LSB) to provide an output current which accurately balances the input signal current through the 5kΩ input resistor. The comparator determines whether the addition of each successively weighted bit current causes the DAC current sum to be greater or less than the input current. If the sum is less, the bit is left on; if more, the bit is turned off. After testing all the bits, the SAR contains a 10-bit binary code which accurately represents the input signal to within ±1/2LSB (0.05%).

Upon completion of the sequences, the SAR sends out a $\overline{\text{DATA READY}}$ signal (active low), which also brings the three-state buffers out of their "open" state, making the bit output lines become active high or low, depending on the code in the SAR. When the BLANK and $\overline{\text{CONVERT}}$ line is brought high, the output buffers again go "open", and the SAR is prepared for another conversion cycle. Details of the timing are given further on.

The temperature compensated buried Zener reference provides the primary voltage reference to the DAC and guarantees excellent stability with both time and temperature. The bipolar offset input controls a switch which allows a positive bipolar offset current to be injected into the summing (+) node of the comparator to offset the DAC output. The nominal 0 to +10V unipolar input range now becomes a −5V to +5V range. The 5kΩ thin-film input resistor is trimmed so that with a full-scale input signal, an input current will be generated which exactly matches the DAC output with all bits on. (The input resistor is trimmed slightly low to facilitate user trimming, as discussed on the next page.)

POWER SUPPLY SELECTION



The AD570/AD571 are designed for optimum performance using a +5V and −15V supply, for which the J and S grades are specified. AD571K will also operate with up to a +15V supply, which allows direct interface to CMOS logic.

AD570/AD571 Functional Block Diagram

CONNECTING THE AD570/AD571 FOR STANDARD OPERATION

The AD570/AD571 contain all the active components required to perform a complete A/D conversion. Thus, for most situations, all that is necessary is connection of the power supply (+5 and −15), the analog input, and the conversion start pulse. The functional pin outs are shown below.

AD570 Pin Connections *AD571 Pin Connections*

FULL-SCALE CALIBRATION

The 5kΩ thin-film input resistor is laser trimmed to produce a current which matches the full-scale current of the internal DAC when a full-scale analog input voltage of 10 volts – 1LSB is applied at the input. The input resistor is trimmed in this way so that if a fine-trimming potentiometer is inserted in series with the input signal, the input current at the full-scale input voltage can be trimmed down to match the DAC full-scale current as precisely as desired. However, for many applications the nominal 9.990 (9.961 for the AD570) volt full scale can be achieved to sufficient accuracy by simply inserting a 15Ω resistor in series with the analog input to Pin 13. Typical full-scale calibration error will then be about ±2LSB. If the more precise calibration is desired, a trimmer should be used instead. A 50Ω potentiometer should be used with the AD571 and a 200Ω with the AD570. Set the analog input at full scale and set the trimmer so that the output code is just at the transition between 1111111110 and 1111111111. Each LSB will then have a weight of $10V/2^N$ (where N = number of bits).

BIPOLAR OPERATION

The standard unipolar 0 to +10V range is obtained by shorting the bipolar offset control pin to digital common. If the pin is left open, the bipolar offset current will be switched into the comparator summing node, giving a −5V to +5V range with an offset binary code. The bipolar offset control input is not directly TTL compatible, but a TTL interface for logic control can be constructed as shown in Figure 1.

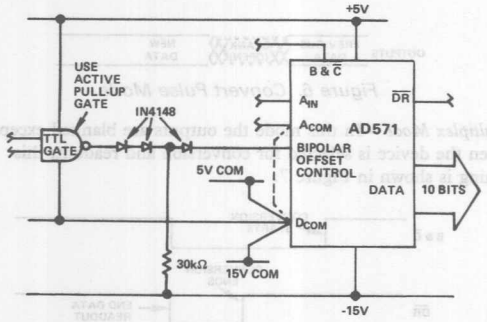


Figure 1. Bipolar Offset Controlled by Logic Gate
Gate Output = 1 Unipolar 0 – 10V Input Range
Gate Output = 0 Bipolar ±5V Input Range

COMMON-MODE RANGE

The AD570/AD571 provide separate analog and digital common connections. The circuit will operate properly with as much as ±200mV of common-mode range between the two commons. This permits more flexible control of system common bussing and digital and analog return.

In normal operation the analog common terminal may generate transient currents of up to 2mA during a conversion. In addition, a static current of about 2mA will flow into analog common in the unipolar mode after a conversion is complete. An additional 1mA will flow in during a blank interval with zero analog input. The analog common current will be modulated by the variations in input signal.

The absolute maximum voltage rating between the two commons is ±1 volt. We recommend the connection of a parallel pair of back-to-back protection diodes between the commons if they are not connected locally.

ZERO OFFSET

The apparent zero point of the AD570/AD571 can be adjusted by inserting an offset voltage between the analog common of the device and the actual signal return or signal common. Figure 2 illustrates two methods of providing this offset for the AD571. Figure 2a shows how the converter zero may be offset by up to ±3 bits to correct the device initial offset and/or input signal offsets. As shown, the circuit gives approximately symmetrical adjustment in unipolar mode. In bipolar mode R2 should be omitted to obtain a symmetrical range.

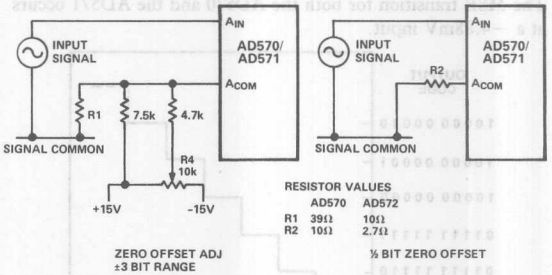

Figure 2a. *Figure 2b.*

Figure 3 shows the nominal transfer curve near zero for an AD571 in unipolar mode. The code transitions are at the edges of the nominal bit weights. In some applications it will be preferable to offset the code transitions so that they fall between the nominal bit weights, as shown in the offset characteristics. This offset can easily be accomplished as shown in Figure 2b. At balance

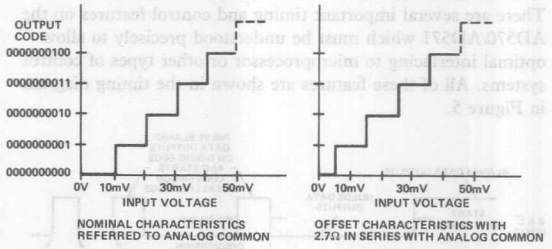

Figure 3. AD571 Transfer Curve – Unipolar Operation (Approximate Bit Weights Shown for Illustration, Nominal Bit Weights~9.755mV)

(after a conversion) approximately 2mA flows into the analog common terminal. A 2.7Ω resistor in series with this terminal will result in approximately the desired 1/2 bit offset of the transfer characteristics. The nominal 2mA analog common current is not closely controlled in manufacture. If high accuracy is required, a 5Ω potentiometer (connected as a rheostat) can be used as R1. Additional negative offset range may be obtained by using larger values of R1. Of course, if the zero transition point is changed, the full-scale transition point will also move. Thus, if an offset of 1/2LSB is introduced, full-scale trimming as previously described should be done with an analog input of 9.985 volts.

NOTE: During a conversion transient currents from the analog common terminal will disturb the offset voltage. Capacitive

decoupling will "pump up" and fail to settle resulting in conversion errors. Power supply decoupling, which returns to analog signal common, should go to the signal input side of the resistive offset network.

BIPOLAR CONNECTION

To obtain the bipolar −5V to +5V range with an offset binary output code the bipolar offset control pin is left open.

A −5.0 volt signal will give a 10-bit code of 00000000 00; an input of 0.00 volts results in an output code of 10000000 00 and +4.99 volts at the input yields the 11111111 11 code. The nominal transfer curve for the AD571 is shown in Figure 4. The MSB transition for both the AD570 and the AD571 occurs at a −4.88mV input.

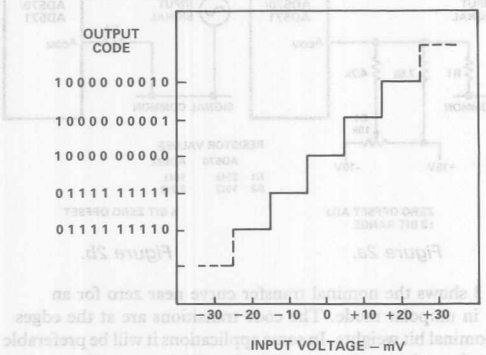

Figure 4. AD571 Transfer Curve – Bipolar Operation

CONTROL AND TIMING OF THE AD570/AD571

There are several important timing and control features on the AD570/AD571 which must be understood precisely to allow optimal interfacing to microprocessor or other types of control systems. All of these features are shown in the timing diagram in Figure 5.

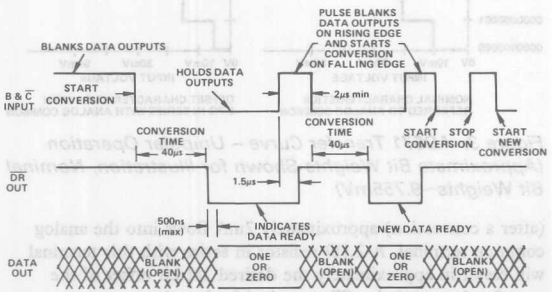

Figure 5. AD570/AD571 Timing and Control Sequences

The normal standby situation is shown at the left end of the drawing. The BLANK and $\overline{\text{CONVERT}}$ (B & $\overline{\text{C}}$) line is held high, the output lines will be "open", and the $\overline{\text{DATA READY}}$ ($\overline{\text{DR}}$) line will be high. This mode is the lowest power state of the device (typically 150mW). When the (B & $\overline{\text{C}}$) line is brought low, the conversion cycle is initiated; but the $\overline{\text{DR}}$ and data lines do not change state. When the conversion cycle is complete (typically 25μs), the $\overline{\text{DR}}$ line goes low, and within 500ns, the

About 1.5μs after the B & $\overline{\text{C}}$ line is again brought high, the $\overline{\text{DR}}$ will go high and the data lines will go open. When the B & $\overline{\text{C}}$ line is again brought low, a new conversion will begin. The minimum pulse width for the B & $\overline{\text{C}}$ line to blank previous data and start a new conversion is 2μs. If the the B & $\overline{\text{C}}$ line is brought high during a conversion, the conversion will stop, and the $\overline{\text{DR}}$ and data lines will not change. If a 2μs or longer pulse is applied to the B & $\overline{\text{C}}$ line during a conversion, the converter will clear and start a new conversion cycle.

CONTROL MODES WITH BLANK AND $\overline{\text{CONVERT}}$

The timing sequence of the AD570/AD571 discussed above allows the devices to be easily operated in a variety of systems with differing control modes. The two most common control modes, the convert pulse mode and the multiplex mode, are illustrated here.

Convert Pulse Mode – In this mode, data is present at the output of the converter at all times except when conversion is taking place. Figure 6 illustrates the timing of this mode. The BLANK and $\overline{\text{CONVERT}}$ line is normally low and conversions are triggered by a positive pulse.

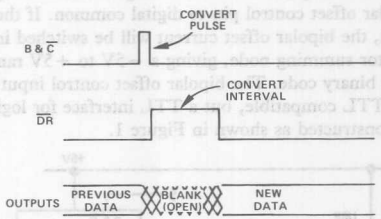

Figure 6. Convert Pulse Mode

Multiplex Mode – In this mode the outputs are blanked except when the device is selected for conversion and readout; this timing is shown in Figure 7.

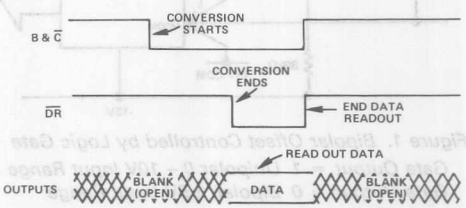

Figure 7. Multiplex Mode

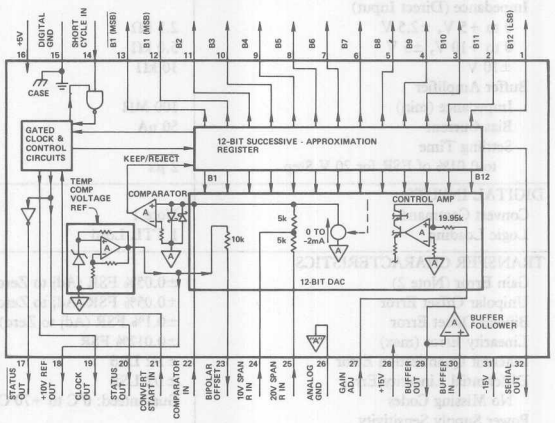
This operating mode allows multiple converters to drive common data lines. All BLANK and $\overline{\text{CONVERT}}$ lines are held high to keep the outputs blanked. A single AD571 is selected, its BLANK and $\overline{\text{CONVERT}}$ line is driven low and at the end of conversion, which is indicated by $\overline{\text{DATA READY}}$ going low, the conversion result will be present at the outputs. When this data has been read from the 10-bit bus, BLANK and $\overline{\text{CONVERT}}$ is restored to the blank mode to clear the data bus for other converters. When several converters are multiplexed in sequence, a new conversion may be started in one AD570/AD571 while data is being read from another. As long as the data is read and the first AD570/AD571 is cleared within 15μs after the start of conversion of the second AD570/AD571, no data overlap will occur.

12-Bit Successive Approximation Integrated Circuit A/D Converter

AD572*



FEATURES

PERFORMANCE
- True 12-Bit Operation: Max Nonlinearity <±0.012%
- Low Gain T.C.: < ±15 ppm/°C (AD572B)
- Low Power: 900 mW
- Fast Conversion Time: < 25 μs
- Monotonic Feedback DAC Guarantees No Missing Codes

VERSATILITY
- Aerospace Temperature Range: −55°C to +125°C (AD572S)
- Positive-True Serial or Parallel Logic Outputs
- Short-Cycle Capability

VALUE
- Precision +10 V Reference for External Application
- Internal Buffer Amplifier
- High Reliability Package

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD572 is a complete 12-bit successive approximation analog-to-digital converter that includes an internal clock, reference, comparator, and buffer amplifier. Its hybrid IC design utilizes MSI digital and linear monolithic chips and active laser trimming of high-stability thin-film resistors to provide superior performance, flexibility and ease of use, combined with IC size, price, and reliability.

Important performance characteristics of the AD572 include a maximum linearity error at 25°C of ±0.012%, gain T.C. below 15 ppm/°C, typical power dissipation of 900 mW, and conversion time of less than 25 μs. Of considerable significance in aerospace applications is the guaranteed performance from −55°C to +125°C of the AD572S. Monotonic operation of the feedback D/A converter guarantees no missing output codes over temperature ranges of 0°C to +70°C, −25°C to +85°C, and −55°C to +125°C.

The design of the AD572 includes scaling resistors that provide analog input signal ranges of ±2.5, ±5.0, ±10, 0 to +5, or 0 to +10 volts. Adding flexibility and value are the +10 V precision reference, which also can be used for external applications, and the input buffer amplifier. All digital signals are fully TTL compatible, and the data output is positive-true and available in either serial or parallel form.

The AD572 is available in three versions with differing guaranteed performance characteristics and operating temperature ranges; the "A" and "B" are specified from −25°C to +85°C, and the "S" from −55°C to +125°C.

PRODUCT DESCRIPTION

The AD572 functional diagram and pinout are shown above. The device consists of the following monolithic bipolar circuit elements:

1. Twelve-bit successive-approximation register
2. Twelve-bit DAC
3. Low-drift comparator
4. Temperature-compensated precision +10 V reference
5. High-impedance buffer follower
6. Gated clock and digital control circuits

10-Bit A/D Converter

AD573*

FEATURES

- **Complete 10-Bit A/D Converter with Reference, Clock and Comparator**
- **Full 8- or 16-Bit Microprocessor Bus Interface**
- **Fast Successive Approximation Conversion – 20μs typ**
- **No Missing Codes Over Temperature**
- **Operates on +5V and −12V to −15V Supplies**
- **Low Cost Monolithic Construction**

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD573 is a complete 10-bit successive approximation analog to digital converter consisting of a DAC, voltage reference, clock, comparator, successive approximation register (SAR) and 3 state output buffers–all fabricated on a single chip. No external components are required to perform a full accuracy 10-bit conversion in 20μs.

The AD573 incorporates advanced integrated circuit design and processing technologies. The successive approximation function is implemented with I^2L (integrated injection logic). Laser trimming of the high stability SiCr thin film resistor ladder network insures high accuracy, which is maintained with a temperature compensated sub-surface Zener reference.

Operating on supplies of +5V and −12V to −15V, the AD573 will accept analog inputs of 0 to +10V or −5V to +5V. The trailing edge of a positive pulse on the CONVERT line initiates the 20μs conversion cycle. DATA READY indicates completion of the conversion. HIGH BYTE ENABLE (HBE) and LOW BYTE ENABLE (LBE) control the 8-bit and 2-bit three state output buffers.

The AD573 is available in two versions for the 0 to +70°C temperature range, the AD573J and AD573K. The AD573S guarantees ±1LSB relative accuracy and no missing codes from −55°C to +125°C.

Three package configurations are offered. All versions are offered in a 20-pin hermetically sealed ceramic DIP. The AD573J and AD573K are also available in a 20-pin plastic DIP or 20-pin leaded chip carrier.

PRODUCT HIGHLIGHTS

1. The AD573 is a complete 10-bit A/D converter. No external components are required to perform a conversion.
2. The AD573 interfaces to many popular microprocessors without external buffers or peripheral interface adapters. The 10 bits of output data can be read as a 10-bit word or as 8- and 2-bit words.
3. The device offers true 10-bit accuracy and exhibits no missing codes over its entire operating temperature range.
4. The AD573 adapts to either unipolar (0 to +10V) or bipolar (−5V to +5V) analog inputs by simply grounding or opening a single pin.
5. Performance is guaranteed with +5V and −12V or −15V supplies.
6. The AD573 is available in a version compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current /883B datasheet for detailed specifications.

NOTES

[1]Relative accuracy is defined as the deviation of the code transition points from the ideal transfer point on a straight line from the zero to the full scale of the device.

[2]Full-scale calibration is guaranteed trimmable to zero with an external 50Ω potentiometer in place of the 15Ω fixed resistor. Full scale is defined as 10 volts minus 1LSB, or 9.990 volts.

[3]Defined as the resolution for which no missing codes will occur.

[4]Change from +25°C value from +25°C to T_{min} or T_{max}.

[5]The data output lines have active pull-ups to source 0.5mA. The $\overline{\text{DATA READY}}$ line is open collector with a nominal 6kΩ internal pull-up resistor.

Specifications subject to change without notice.

Specifications shown in boldface are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

FUNCTIONAL DESCRIPTION

A block diagram of the AD573 is shown in Figure 1. The positive CONVERT pulse must be at least 500ns wide. $\overline{DR}$ goes high within 1.5μs after the leading edge of the convert pulse indicating that the internal logic has been reset. The negative edge of the CONVERT pulse initiates the conversion. The internal 10-bit current output DAC is sequenced by the integrated injection logic (I^2L) successive approximation register (SAR) from its most significant bit to least significant bit to provide an output current which accurately balances the input signal current through the 5kΩ resistor. The comparator determines whether the addition of each successively weighted bit current causes the DAC current sum to be greater or less than the input current; if the sum is more, the bit is turned off. After testing all bits, the SAR contains a 10-bit binary code which accurately represents the input signal to within ½LSB (0.05% of full scale).

The SAR drives $\overline{DR}$ low to indicate that the conversion is complete and that the data is available to the output buffers. $\overline{HBE}$ and $\overline{LBE}$ can then be activated to enable the upper 8-bit and lower 2-bit buffers as desired. $\overline{HBE}$ and $\overline{LBE}$ should be brought high prior to the next conversion to place the output buffers in the high impedance state.

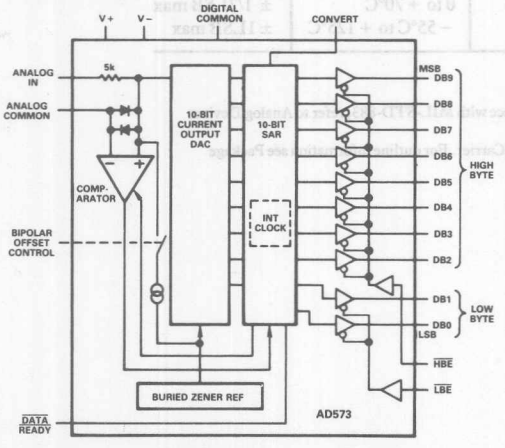

Figure 1. AD573 Functional Block Diagram

The temperature compensated buried Zener reference provides the primary voltage reference to the DAC and ensures excellent stability with both time and temperature. The bipolar offset input controls a switch which allows the positive bipolar offset current (exactly equal to the value of the MSB less ½LSB) to be injected into the summing (+) node of the comparator to offset the DAC output. Thus the nominal 0 to +10V unipolar input range becomes a −5V to +5V range. The 5kΩ thin film input resistor is trimmed so that with a full scale input signal, an input current will be generated which exactly matches the DAC output with all bits on.

UNIPOLAR CONNECTION

The AD573 contains all the active components required to perform a complete A/D conversion. Thus, for many applications, all that is necessary is connection of the power supplies (+5V and −12V to −15V), the analog input and the convert pulse. However, there are some features and special connections which should be considered for achieving optimum performance. The functional pin-out is shown in Figure 2.

The standard unipolar 0 to +10V range is obtained by shorting the bipolar offset control pin (pin 16) to digital common (pin 17).

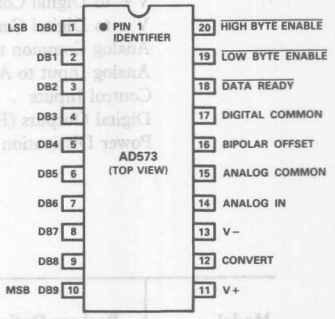

Figure 2. AD573 Pin Connections

Full Scale Calibration

The 5kΩ thin film input resistor is laser trimmed to produce a current which matches the full scale current of the internal DAC–plus about 0.3%–when an analog input voltage of 9.990 volts (10 volts – 1LSB) is applied at the input. The input resistor is trimmed in this way so that if a fine trimming potentiometer is inserted in series with the input signal, the input current at the full scale input voltage can be trimmed down to match the DAC full scale current as precisely as desired. However, for many applications the nominal 9.99 volt full scale can be achieved to sufficient accuracy by simply inserting a 15Ω resistor in series with the analog input to pin 14. Typical full scale calibration error will then be within ±2LSB or ±0.2%. If more precise calibration is desired, a 50Ω trimmer should be used instead. Set the analog input at 9.990 volts, and set the trimmer so that the output code is just at the transition between 11111111 10 and 11111111 11. Each LSB will then have a weight of 9.766mV. If a nominal full scale of 10.24 volts is desired (which makes the LSB have a weight of exactly 10.00mV), a 100Ω resistor and a 100Ω trimmer (or a 200Ω trimmer with good resolution) should be used. Of course, larger full scale ranges can be arranged by using a larger input resistor, but linearity and full scale temperature coefficient may be compromised if the external resistor becomes a sizeable percentage of 5kΩ. Figure 3 illustrates the connections required for full scale calibration.

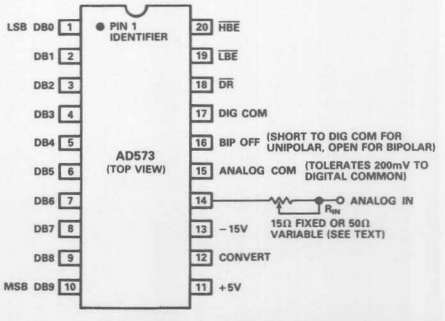

Figure 3. Standard AD573 Connections

Unipolar Offset Calibration

Since the Unipolar Offset is less than ±1LSB for all versions of the AD573, most applications will not require trimming. Figure 4 illustrates two trimming methods which can be used if greater accuracy is necessary.

Figure 4a shows how the converter zero may be offset by up to ±3 bits to correct the device initial offset and/or input signal offsets. As shown, the circuit gives approximately symmetrical adjustment in unipolar mode.

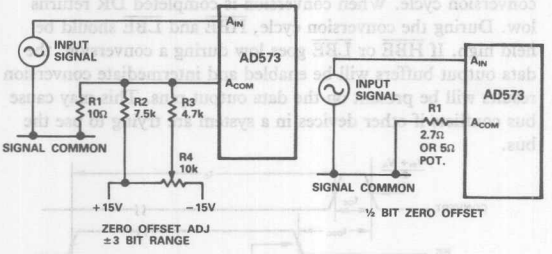

Figure 4a. *Figure 4b.*

Figure 4. Offset Trims

Figure 5 shows the nominal transfer curve near zero for an AD573 in unipolar mode. The code transitions are at the edges of the nominal bit weights. In some applications it will be preferable to offset the code transitions so that they fall between the nominal bit weights, as shown in the offset characteristics.

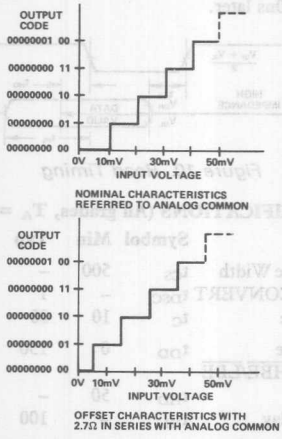

Figure 5. AD573 Transfer Curve – Unipolar Operation (Approximate Bit Weights Shown for Illustration, Nominal Bit Weights ~ 9.766mV)

This offset can easily be accomplished as shown in Figure 4b. At balance (after a conversion) approximately 2mA flows into the Analog Common terminal. A 2.7Ω resistor in series with this terminal will result in approximately the desired ½ bit offset of the transfer characteristics. The nominal 2mA Analog Common current is not closely controlled in manufacture. If high accuracy is required, a 5Ω potentiometer (connected as a rheostat) can be used as R1. Additional negative offset range may be obtained by using larger values of R1. Of course, if the zero transition point is changed, the full scale transition point will also move. Thus, if an offset of ½LSB is introduced, full scale trimming as described on the previous page should be done with an analog input of 9.985 volts.

NOTE: During a conversion, transient currents from the Analog Common terminal will disturb the offset voltage. Capacitive decoupling should not be used around the offset network. These transients will settle appropriately during a conversion. Capacitive decoupling will "pump up" and fail to settle resulting in conversion errors. Power supply decoupling, which returns to analog signal common, should go to the signal input side of the resistive offset network.

BIPOLAR CONNECTION

To obtain the bipolar −5V to +5V range with an offset binary output code, the bipolar offset control pin is left open.

A −5.000 volt signal will give a 10-bit code of 00000000 00; an input of 0.000 volts results in an output code of 10000000 00 and +4.99 volts at the input yields the 11111111 11 code. The nominal transfer curve is shown in Figure 6.

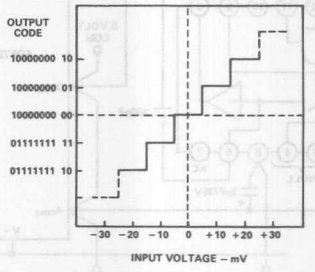

Figure 6. AD573 Transfer Curve – Bipolar Operation

Note that in the bipolar mode, the code transitions are offset ½LSB such that an input voltage of 0 volts ±5mV yields the code representing zero (10000000 00). Each output code is then *centered* on its nominal input voltage.

Full Scale Calibration

Full Scale Calibration is accomplished in the same manner as in Unipolar operation except the full scale input voltage is +4.985 volts.

Negative Full Scale Calibration

The circuit in Figure 4a can also be used in Bipolar operation to offset the input voltage (nominally −5V) which results in the 00000000 00 code. R2 should be omitted to obtain a symmetrical range.

The bipolar offset control input is not directly TTL compatible but a TTL interface for logic control can be constructed as shown in Figure 7.

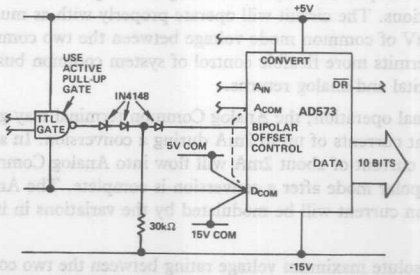

Figure 7. Bipolar Offset Controlled by Logic Gate
Gate Output = 1 Unipolar 0 – 10V Input Range
Gate Output = 0 Bipolar ±5V Input Range

SAMPLE-HOLD AMPLIFIER CONNECTION TO THE AD573

Many situations in high-speed acquisition systems or digitizing rapidly changing signals require a sample-hold amplifier (SHA) in front of the A-D converter. The SHA can acquire and hold a

signal faster than the converter can perform a conversion. A SHA can also be used to accurately define the exact point in time at which the signal is sampled. For the AD573, a SHA can also serve as a high input impedance buffer.

Figure 8 shows the AD573 connected to the AD582 monolithic SHA for high speed signal acquisition. In this configuration, the AD582 will acquire a 10 volt signal in less than 10μs with a droop rate less than 100μV/ms.

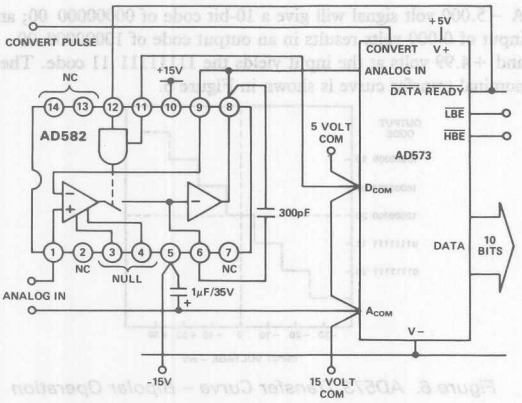

Figure 8. Sample-Hold Interface to the AD573

$\overline{DR}$ goes high after the conversion is initiated to indicate that reset of the SAR is complete. In Figure 8 it is also used to put the AD582 into the hold mode while the AD573 begins its conversion cycle. (The AD582 settles to final value well in advance of the first comparator decision inside the AD573).

$\overline{DR}$ goes low when the conversion is complete placing the AD582 back in the sample mode. Configured as shown in Figure 8, the next conversion can be initiated after a 10μs delay to allow for signal acquisition by the AD582.

Observe carefully the ground, supply, and bypass capacitor connections between the two devices. This will minimize ground noise and interference during the conversion cycle.

GROUNDING CONSIDERATIONS

The AD573 provides separate Analog and Digital Common connections. The circuit will operate properly with as much as ±200mV of common mode voltage between the two commons. This permits more flexible control of system common bussing and digital and analog returns.

In normal operation, the Analog Common terminal may generate transient currents of up to 2mA during a conversion. In addition a static current of about 2mA will flow into Analog Common in the unipolar mode after a conversion is complete. The Analog Common current will be modulated by the variations in input signal.

The absolute maximum voltage rating between the two commons is ±1 volt. It is recommended that a parallel pair of back-to-back protection diodes be connected between the commons if they are not connected locally.

CONTROL AND TIMING OF THE AD573

The operation of the AD573 is controlled by three inputs: CONVERT, $\overline{HBE}$ and $\overline{LBE}$.

Starting a Conversion

The conversion cycle is initiated by a positive-going CONVERT pulse at least 500ns wide. The rising edge of this pulse resets the internal logic, clears the result of the previous conversion, and sets $\overline{DR}$ high. The falling edge of CONVERT begins the conversion cycle. When conversion is completed $\overline{DR}$ returns low. During the conversion cycle, $\overline{HBE}$ and $\overline{LBE}$ should be held high. If $\overline{HBE}$ or $\overline{LBE}$ goes low during a conversion, the data output buffers will be enabled and intermediate conversion results will be present on the data output pins. This may cause bus conflicts if other devices in a system are trying to use the bus.

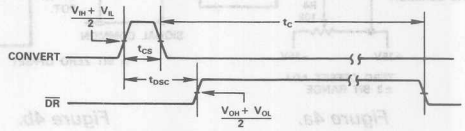

Figure 9. Convert Timing

Reading the Data

The three-state data output buffers are enabled by $\overline{HBE}$ and $\overline{LBE}$. Access time of these buffers is typically 150ns (250 maximum). The Data outputs remain valid until 50ns after the enable signal returns high, and are completely into the high-impedance state 100ns later.

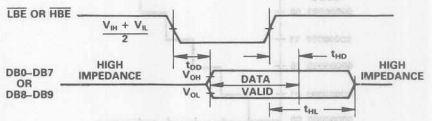

Figure 10. Read Timing

TIMING SPECIFICATIONS (All grades, $T_A = T_{min} - T_{max}$)

Parameter	Symbol	Min	Typ	Max	Units
CONVERT Pulse Width	t_{CS}	500	–	–	ns
$\overline{DR}$ Delay from CONVERT	t_{DSC}	–	1	1.5	μs
Conversion Time	t_C	10	20	30	μs
Data Access Time	t_{DD}	0	150	250	ns
Data Valid after $\overline{HBE}$/$\overline{LBE}$ High	t_{HD}	50	–	–	ns
Output Float Delay	t_{HL}	–	100	200	ns

MICROPROCESSOR INTERFACE CONSIDERATIONS – GENERAL

When an analog-to-digital converter like the AD573 is interfaced to a microprocessor, several details of the interface must be considered. First, a signal to start the converter must be generated; then an appropriate delay period must be allowed to pass before valid conversion data may be read. In most applications, the AD573 can interface to a microprocessor system with little or no external logic.

The most popular control signal configuration consists of decoding the address assigned to the AD573, then gating this signal with the system's WR signal to generate the CONVERT pulse, and gating it with RD to enable the output buffers. The use of a memory address and memory WR and RD signals denotes "memory-mapped" I/O interfacing, while the use of a separate I/O address space denotes "isolated I/O" interfacing. In 8-bit bus systems, the 10-bit AD573 will occupy two locations when data is to be read; therefore, two (usually consecutive) addresses must be decoded. One of the addresses can also be used as

the address which produces the CONVERT signal during WR operations.

Figure 11 shows a generalized diagram of the control logic for an AD573 interfaced to an 8-bit data bus, where two addresses (ADC ADDR and ADC ADDR + 1) have been decoded. ADC ADDR starts the converter when written to (the actual data being written to the converter does not matter) and contains the high byte data during read operations. ADC ADDR + 1 performs no function during write operations, but contains the low byte data during read operations.

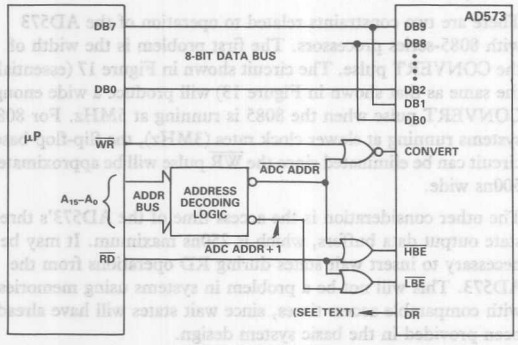

Figure 11. General AD573 Interface to 8-Bit Microprocessor

In systems where this read-write interface is used, at least 30 microseconds (the maximum conversion time) must be allowed to pass between starting a conversion and reading the results. This delay or "timeout" period can be implemented in a short software routine such as a countdown loop, enough dummy instructions to consume 30 microseconds, or enough actual useful instructions to consume the required time. In tightly-timed systems, the $\overline{DR}$ line may be read through an external three-state buffer to determine precisely when a conversion is complete. Higher-speed systems may choose to use $\overline{DR}$ to signal an interrupt to the processor at the end of a conversion.

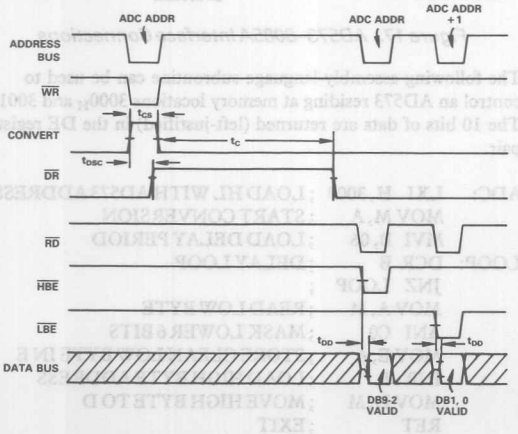

Figure 12. Typical AD573 Interface Timing Diagram

CONVERT Pulse Generation

The AD573 is tested with a CONVERT pulse width of 500ns and will typically operate with a pulse as short as 300ns. However, some microprocessors produce active WR pulses which are shorter than this. Either of the circuits shown in Figure 13 can be used to generate an adequate CONVERT pulse for the AD573.

In both circuits, the short low-going WR pulse sets the CONVERT line high through a flip-flop. The rising edge of $\overline{DR}$ (which signifies that the internal logic has been reset) resets the flip-flop and brings CONVERT low, which starts the conversion.

Note that t_{DSC} is slightly longer when the result of the previous conversion contains a logic 1 on the LSB. This means that the actual CONVERT pulse generated by the circuits in Figure 13 will vary slightly in width.

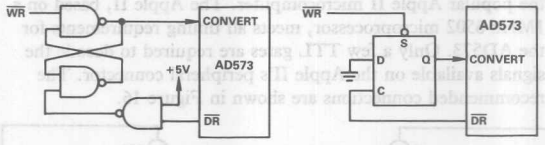

Figure 13a. Using 74LS00 *Figure 13b. Using 1/2 74LS74*

Output Data Format

The AD573 output data is presented in a left-justified format. The 8 MSBs (DB9–DB2, pins 10 through 3) are enabled by $\overline{HBE}$ (pin 20) and the 2 LSBs (DB1, DB0 – pins 2 and 1) are enabled by $\overline{LBE}$ (pin 19). This allows simple interface to 8-bit system buses by overlapping the 2 MSBs and the 2 LSBs. The organization of the data is shown in Figure 14.

When the least significant bits are read ($\overline{LBE}$ brought low), the six remaining bits of the byte will contain meaningless data. These unwanted bits can be masked by logically ANDing the byte with 11000000 (C0 hex), which forces the 6 lower bits to logic 0 while preserving the two most significant bits of the byte.

Note that it is not possible to reconfigure the AD573 for right justified data.

$\overline{HBE}$	DB9	DB8	DB7	DB6	DB5	DB4	DB3	DB2
$\overline{LBE}$	DB1	DB0	X	X	X	X	X	X

Figure 14. AD573 Output Data Format

In systems where all 10 bits are desired at the same time, $\overline{HBE}$ and $\overline{LBE}$ may be tied together. This is useful in interfacing to 16-bit bus systems. The resulting 10-bit word can then be placed at the high end of the 16-bit bus for left justification or at the low end for right justification.

It is also possible to use the AD573 in a "stand-alone" mode, where the output data buffers are automatically enabled at the end of a conversion cycle. In this mode, the $\overline{DR}$ output is wired to the $\overline{HBE}$ and $\overline{LBE}$ inputs. The outputs thus are forced into the high-impedance state during the conversion period, and valid data becomes available approximately 500ns after the $\overline{DR}$ signal goes low at the end of the conversion. The 500ns delay allows propagation of the least significant bit through the internal logic.

This mode is particularly useful for bench-testing of the AD573, and in applications where dedicated I/O ports of peripheral interface adapter chips are available.

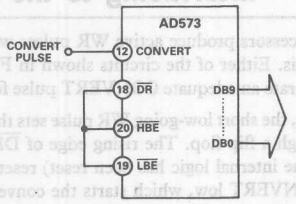

Figure 15. AD573 in "Stand-Alone" Mode (Output Data Valid 500ns After DR Goes Low)

Apple II Microcomputer Interface

The AD573 can provide a flexible, low-cost analog interface for the popular Apple II microcomputer. The Apple II, based on a 1MHz 6502 microprocessor, meets all timing requirements for the AD573. Only a few TTL gates are required to decode the signals available on the Apple II's peripheral connector. The recommended connections are shown in Figure 16.

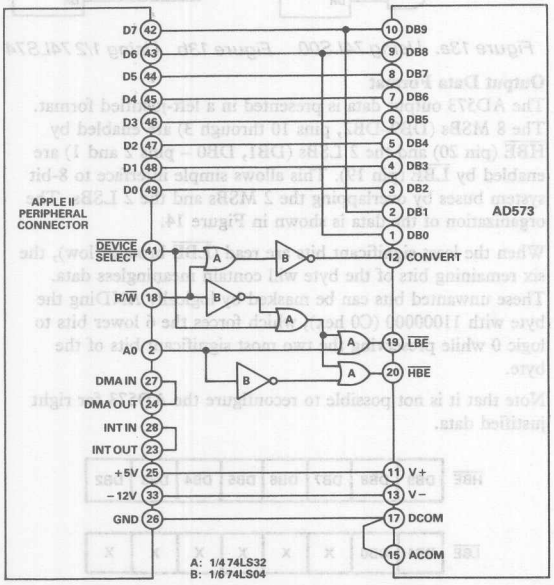

Figure 16. AD573 Interface to Apple II

The BASIC routine listed here will operate the AD573 circuit shown in Figure 16. The conversion is started by POKEing to the location which contains the AD573. The relatively slow execution speed of BASIC eliminates the need for a delay routine between starting and reading the converter. This routine assumes that the AD573 is connected for a ±5 volt input range. Variable I represents the integer value (from 0 to 1023) read from the AD573. Variable V represents the actual value of the input signal (in volts).

```
100 PRINT "WHICH SLOT IS THE A/D IN";:INPUT S
110 A= 49280+16*S
120 POKE A,0
130 L=PEEK(A) :H=PEEK(A+1)
140 I=(4*H)+INT(L/64)
150 V=(I/1024)*10-5
160 PRINT "THE INPUT SIGNAL IS ";V;"VOLTS."
```

It is also possible to write a faster-executing assembly-language routine to control the AD573. Such a routine will require a delay between starting and reading the converter. This can be easily implemented by calling the Apple's WAIT subroutine (which resides at location $FCA8) after loading the accumulator with a number greater than or equal to two.

8085-Series Microprocessor Interface

The AD573 can also be used with 8085-series microprocessors. These processors use separate control signals for RD and WR, as opposed to the single R/$\overline{W}$ control signal used in the 6800/6500 series processors.

There are two constraints related to operation of the AD573 with 8085-series processors. The first problem is the width of the CONVERT pulse. The circuit shown in Figure 17 (essentially the same as that shown in Figure 13) will produce a wide enough CONVERT pulse when the 8085 is running at 5MHz. For 8085 systems running at slower clock rates (3MHz), the flip-flop-based circuit can be eliminated since the $\overline{WR}$ pulse will be approximately 500ns wide.

The other consideration is the access time of the AD573's three-state output data buffers, which is 250ns maximum. It may be necessary to insert wait states during RD operations from the AD573. This will not be a problem in systems using memories with comparable access times, since wait states will have already been provided in the basic system design.

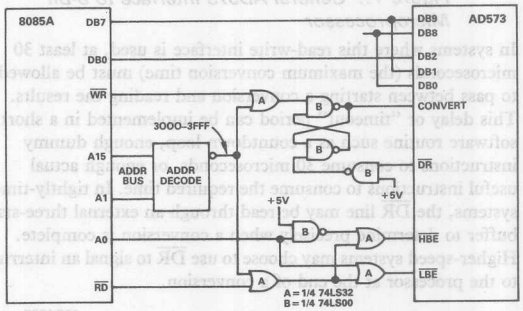

Figure 17. AD573–8085A Interface Connections

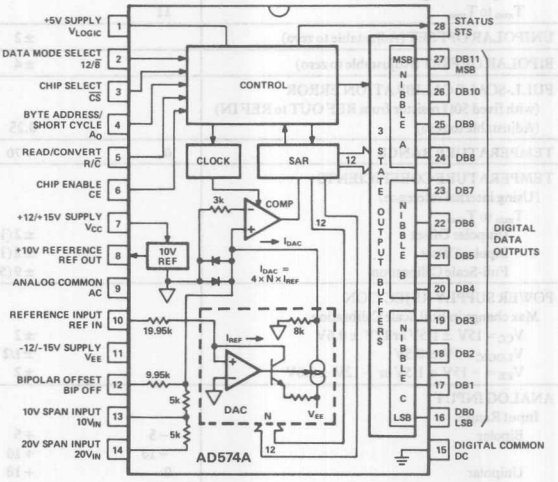
The following assembly-language subroutine can be used to control an AD573 residing at memory locations 3000_H and 3001_H. The 10 bits of data are returned (left-justified) in the DE register pair.

```
ADC:   LXI  H,3000  ;LOAD HL WITH AD573 ADDRESS
       MOV  M,A     ;START CONVERSION
       MVI  B,06    ;LOAD DELAY PERIOD
LOOP:  DCR  B       ;DELAY LOOP
       JNZ  LOOP    ;
       MOV  A,M     ;READ LOW BYTE
       ANI  C0      ;MASK LOWER 6 BITS
       MOV  E,A     ;STORE CLEAN LOW BYTE IN E
       INR  L       ;LOAD HIGH BYTE ADDRESS
       MOV  D,M     ;MOVE HIGH BYTE TO D
       RET          ;EXIT
```



Complete 12-Bit A/D Converter

AD574A*

FEATURES

Complete 12-Bit A/D Converter with Reference and Clock
8- and 16-Bit Microprocessor Bus Interface
Guaranteed Linearity Over Temperature
0 to +70°C – AD574AJ, K, L
−55°C to +125°C – AD574AS, T, U
No Missing Codes Over Temperature
35µs Maximum Conversion Time
Buried Zener Reference for Long-Term Stability and Low Gain T.C. 10ppm/°C max AD574AL
12.5ppm/°C max AD574AU
Ceramic DIP, Plastic DIP or PLCC Package
Available in Higher Speed, Pinout-Compatible Versions (15µs AD674B, 8µs AD774B; 10µs (with SHA) AD1674)
Available in Versions Compliant with MIL-STD-883 and JAN QPL.

BLOCK DIAGRAM AND PIN CONFIGURATION

PRODUCT DESCRIPTION

The AD574A is a complete 12-bit successive-approximation analog-to-digital converter with 3-state output buffer circuitry for direct interface to an 8- or 16-bit microprocessor bus. A high-precision voltage reference and clock are included on-chip, and the circuit guarantees full-rated performance without external circuitry or clock signals.

The AD574A design is implemented using Analog Devices' Bipolar/I^2L process, and integrates all analog and digital functions on one chip. Offset, linearity and scaling errors are minimized by active laser-trimming of thin-film resistors at the wafer stage. The voltage reference uses an implanted buried Zener for low noise and low drift. On the digital side, I^2L logic is used for the successive-approximation register, control circuitry and 3-state output buffers.

The AD574A is available in six different grades. The AD574AJ, K, and L grades are specified for operation over the 0 to +70°C temperature range. The AD574AS, T, and U are specified for the −55°C to +125°C range. All grades are available in a 28-pin hermetically-sealed ceramic DIP. Also, the J, K, and L grades are available in a 28-pin plastic DIP and PLCC, and the J and K grades are available in ceramic LCC.

The S, T, and U grades in ceramic DIP or LCC are available with optional processing to MIL-STD-883C Class B; the T and U grades are available as JAN QPL. The Analog Devices' Military Products Databook should be consulted for details on /883B testing of the AD574A.

***Protected by U.S. Patent Nos. 3,803,590; 4,213,806; 4,511,413; RE 28,633.**

PRODUCT HIGHLIGHTS

1. The AD574A interfaces to most 8- or 16-bit microprocessors. Multiple-mode three-state output buffers connect directly to the data bus while the read and convert commands are taken from the control bus. The 12 bits of output data can be read either as one 12-bit word or as two 8-bit bytes (one with 8 data bits, the other with 4 data bits and 4 trailing zeros).
2. The precision, laser-trimmed scaling and bipolar offset resistors provide four calibrated ranges: 0 to +10 and 0 to +20 volts unipolar, −5 to +5 and −10 to +10 volts bipolar. Typical bipolar offset and full-scale calibration errors of ±0.1% can be trimmed to zero with one external component each.
3. The internal buried Zener reference is trimmed to 10.00 volts with 0.2% maximum error and 15ppm/°C typical T.C. The reference is available externally and can drive up to 1.5mA beyond the requirements of the reference and bipolar offset resistors.
4. AD674B (15µs) and AD774B (8µs) provide higher speed, pin compatibility; AD1674 (10µs) includes on-chip Sample-Hold Amplifier (SHA).

NOTES

[1]Detailed Timing Specifications appear in the Timing Section.

[2]12/$\overline{8}$ Input is *not* TTL-compatible and must be hard wired to V_{LOGIC} or Digital Common.

[3]The reference should be buffered for operation on ±12V supplies.

[4]D = Ceramic DIP. For outline information see Package Information section.

Specifications subject to change without notice.

Specifications shown in boldface are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

NOTES
[1]X = Package designator. Available packages are:
D (D-28) for all grades.
E (E-28A) for J and K grades and /883B processed S, T and U grades.
N (N-28) for J, K, and L grades.
P (P-28A)for PLCC in J, K grades.
Example: AD574AKN is K grade in plastic DIP.
[2]For details on grade and package offerings screened in accordance with MIL-STD-883, refer to Analog Devices Military Products Databook.

THE AD574A OFFERS GUARANTEED MAXIMUM LINEARITY ERROR OVER THE FULL OPERATING TEMPERATURE RANGE

DEFINITIONS OF SPECIFICATIONS

LINEARITY ERROR

Linearity error refers to the deviation of each individual code from a line drawn from "zero" through "full scale". The point used as "zero" occurs 1/2LSB (1.22mV for 10 volt span) before the first code transition (all zeros to only the LSB "on"). "Full scale" is defined as a level 1 1/2LSB beyond the last code transition (to all ones). The deviation of a code from the true straight line is measured from the middle of each particular code.

The AD574AK, L, T, and U grades are guaranteed for maximum nonlinearity of ±1/2LSB. For these grades, this means that an analog value which falls exactly in the center of a given code width will result in the correct digital output code. Values nearer the upper or lower transition of the code width may produce the next upper or lower digital output code. The AD574AJ and S grades are guaranteed to ±1LSB max error. For these grades, an analog value which falls within a given code width will result in either the correct code for that region or either adjacent one.

Note that the linearity error is not user-adjustable.

DIFFERENTIAL LINEARITY ERROR (NO MISSING CODES)

A specification which guarantees no missing codes requires that every code combination appear in a monotonic increasing sequence as the analog input level is increased. Thus every code must have a finite width. For the AD574AK, L, T, and U grades, which guarantee no missing codes to 12-bit resolution, all 4096 codes must be present over the entire operating temperature ranges. The AD574AJ and S grades guarantee no missing codes to 11-bit resolution over temperature; this means that all code combinations of the upper 11 bits must be present; in practice very few of the 12-bit codes are missing.

UNIPOLAR OFFSET

The first transition should occur at a level 1/2LSB above analog common. Unipolar offset is defined as the deviation of the actual transition from that point. This offset can be adjusted as discussed on the following two pages. The unipolar offset temperature coefficient specifies the maximum change of the transition point over temperature, with or without external adjustment.

BIPOLAR OFFSET

In the bipolar mode the major carry transition (0111 1111 1111 to 1000 0000 0000) should occur for an analog value 1/2LSB below analog common. The bipolar offset error and temperature coefficient specify the initial deviation and maximum change in the error over temperature.

QUANTIZATION UNCERTAINTY

Analog-to-digital converters exhibit an inherent quantization uncertainty of ±1/2LSB. This uncertainty is a fundamental characteristic of the quantization process and cannot be reduced for a converter of given resolution.

LEFT-JUSTIFIED DATA

The data format used in the AD574A is left-justified. This means that the data represents the analog input as a fraction of full-scale, ranging from 0 to $\frac{4095}{4096}$. This implies a binary point to the left of the MSB.

FULL-SCALE CALIBRATION ERROR

The last transition (from 1111 1111 1110 to 1111 1111 1111) should occur for an analog value 1 1/2LSB below the nominal full scale (9.9963 volts for 10.000 volts full scale). The full-scale calibration error is the deviation of the actual level at the last transition from the ideal level. This error, which is typically 0.05 to 0.1% of full scale, can be trimmed out as shown in Figures 3 and 4.

TEMPERATURE COEFFICIENTS

The temperature coefficients for full-scale calibration, unipolar offset, and bipolar offset specify the maximum change from the initial (25°C) value to the value at T_{min} or T_{max}.

POWER SUPPLY REJECTION

The standard specifications for the AD574A assume use of +5.00 and ±15.00 or ±12.00V supplies. The only effect of power supply error on the performance of the device will be a small change in the full-scale calibration. This will result in a linear change in all lower-order codes. The specifications show the maximum full-scale change from the initial value with the supplies at the various limits.

CODE WIDTH

A fundamental quantity for A/D converter specifications is the code width. This is defined as the range of analog input values for which a given digital output code will occur. The nominal value of a code width is equivalent to 1 least significant bit (LSB) of the full-scale range or 2.44mV out of 10 volts for a 12-bit ADC.

CIRCUIT OPERATION

The AD574A is a complete 12-bit A/D converter which requires no external components to provide the complete successive-approximation analog-to-digital conversion function. A block diagram of the AD574A is shown in Figure 1.

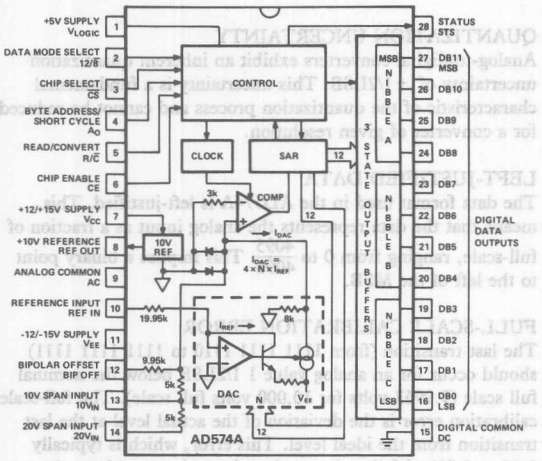

Figure 1. Block Diagram of AD574A 12-Bit A-to-D Converter

When the control section is commanded to initiate a conversion (as described later), it enables the clock and resets the successive-approximation register (SAR) to all zeros. Once a conversion cycle has begun, it cannot be stopped or re-started and data is not available from the output buffers. The SAR, timed by the clock, will sequence through the conversion cycle and return an end-of-convert flag to the control section. The control section will then disable the clock, bring the output status flag low, and enable control functions to allow data read functions by external command.

During the conversion cycle, the internal 12-bit current output DAC is sequenced by the SAR from the most significant bit (MSB) to least significant bit (LSB) to provide an output current which accurately balances the input signal current through the 5kΩ (or 10kΩ) input resistor. The comparator determines whether the addition of each successively-weighted bit current causes the DAC current sum to be greater or less than the input current; if the sum is less, the bit is left on; if more, the bit is turned off. After testing all the bits, the SAR contains a 12-bit binary code which accurately represents the input signal to within ±1/2LSB.

The temperature-compensated buried zener reference provides the primary voltage reference to the DAC and guarantees excellent stability with both time and temperature. The reference is trimmed to 10.00 volts ±0.2%; it can supply up to 1.5mA to an external load in addition to the requirements of the reference input resistor (0.5mA) and bipolar offset resistor (1mA) when the AD574A is powered from ±15V supplies. If the AD574A is used with ±12V supplies, or if external current must be supplied over the full temperature range, an external buffer amplifier is recommended. Any external load on the AD574A reference must remain constant during conversion. The thin-film application resistors are trimmed to match the full-scale output current of the DAC. There are two 5kΩ input scaling resistors to allow either a 10 volt or 20 volt span. The 10kΩ bipolar offset resistor is grounded for unipolar operation and connected to the 10 volt reference for bipolar operation.

DRIVING THE AD574 ANALOG INPUT

The internal circuitry of the AD574 dictates that its analog input be driven by a low source impedance. Voltage changes at the current summing node of the internal comparator result in abrupt modulations of the current at the analog input. For accurate 12-bit conversions the driving source must be capable of holding a constant output voltage under these dynamically changing load conditions.

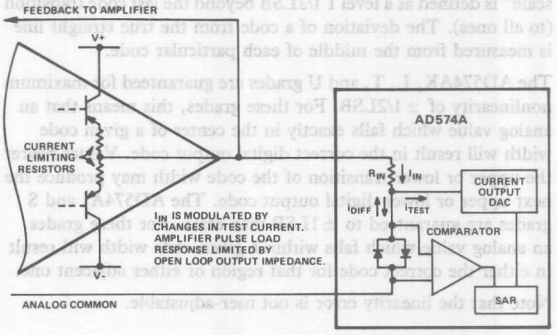

Figure 2. Op Amp – AD574A Interface

The output impedance of an op amp has an open-loop value which, in a closed loop, is divided by the loop gain available at the frequency of interest. The amplifier should have acceptable loop gain at 500kHz for use with the AD574A. To check whether the output properties of a signal source are suitable, monitor the AD574's input with an oscilloscope while a conversion is in progress. Each of the 12 disturbances should subside in 1μs or less.

For applications involving the use of a sample-and-hold amplifier, the AD585 is recommended. The AD711 or AD544 op amps are recommended for dc applications.

SAMPLE-AND-HOLD AMPLIFIERS

Although the conversion time of the AD574A is a maximum of 35μs, to achieve accurate 12-bit conversions of frequencies greater than a few Hz requires the use of a sample-and-hold amplifier (SHA). If the voltage of the analog input signal driving the AD574A changes by more than 1/2LSB over the time interval needed to make a conversion, then the input requires a SHA.

The AD585 is a high-linearity SHA capable of directly driving the analog input of the AD574A. The AD585's fast acquisition time, low aperture and low aperture jitter are ideally suited for high-speed data acquisition systems. Consider the AD574A converter with a 35μs conversion time and an input signal of 10V p-p: the maximum frequency which may be applied to achieve rated accuracy is 1.5Hz. However, with the addition of an AD585, as shown in Figure 3, the maximum frequency increases to 26kHz.

The AD585's low output impedance, fast-loop response, and low droop maintain 12-bits of accuracy under the changing load conditions that occur during a conversion, making it suitable for use in high-accuracy conversion systems. Many other SHAs cannot achieve 12-bits of accuracy and can thus compromise a

system. The AD585 is recommended for AD574A applications requiring a sample and hold.

An alternate approach is to use the AD1674, which combines the ADC and SHA on one chip, with a total throughput time of 10μs.

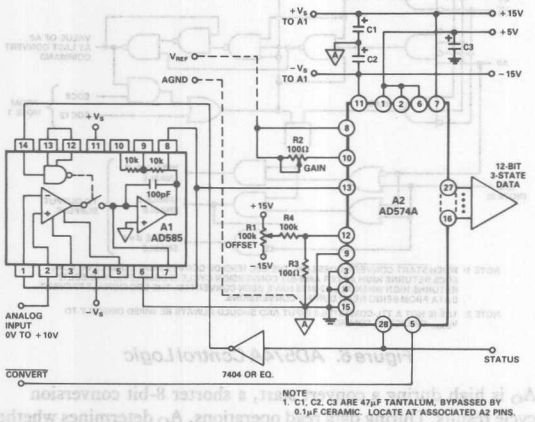

Figure 3. AD574A with AD585 Sample and Hold

SUPPLY DECOUPLING AND LAYOUT CONSIDERATIONS

It is critically important that the AD574A power supplies be filtered, well regulated, and free from high-frequency noise. Use of noisy supplies will cause unstable output codes. Switching power supplies are not recommended for circuits attempting to achieve 12-bit accuracy unless great care is used in filtering any switching spikes present in the output. Remember that a few millivolts of noise represents several counts of error in a 12-bit ADC.

Decoupling capacitors should be used on all power supply pins; the +5V supply decoupling capacitor should be connected directly from pin 1 to pin 15 (digital common) and the $+V_{CC}$ and $-V_{EE}$ pins should be decoupled directly to analog common (pin 9). A suitable decoupling capacitor is a 4.7μF tantalum type in parallel with a 0.1μF disc ceramic type.

Circuit layout should attempt to locate the AD574A, associated analog input circuitry, and interconnections as far as possible from logic circuitry. For this reason, the use of wire-wrap circuit construction is not recommended. Careful printed-circuit construction is preferred.

GROUNDING CONSIDERATIONS

The analog common at pin 9 is the ground reference point for the internal reference and is thus the "high quality" ground for the AD574A; it should be connected directly to the analog reference point of the system. In order to achieve all of the high-accuracy performance available from the AD574A in an environment of high digital noise content, the analog and digital commons should be connected together at the package. In some situations, the digital common at pin 15 can be connected to the most convenient ground reference point; analog power return is preferred.

UNIPOLAR RANGE CONNECTIONS FOR THE AD574A

The AD574A contains all the active components required to perform a complete 12-bit A/D conversion. Thus, for most situations, all that is necessary is connection of the power supplies (+5, +12/+15 and −12/−15 volts), the analog input, and the conversion initiation command, as discussed on the next page. Analog input connections and calibration are easily accomplished; the unipolar operating mode is shown in Figure 4.

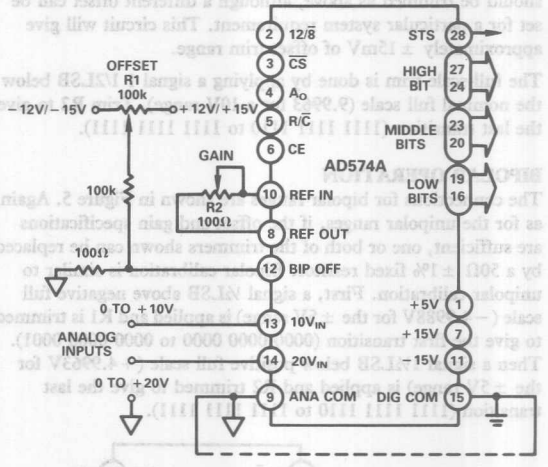

Figure 4. Unipolar Input Connections

All of the thin-film application resistors of the AD574A are trimmed for absolute calibration. Therefore, in many applications, no calibration trimming will be required. The absolute accuracy for each grade is given in the specification tables. For example, if no trims are used, the AD574AK guarantees ±1LSB max zero offset error and ±0.25% (10LSB) max full-scale error. (Typical full-scale error is ±2LSB.) If the offset trim is not required, pin 12 can be connected directly to pin 9; the two resistors and trimmer for pin 12 are then not needed. If the full-scale trim is not needed, a 50Ω ±1% metal film resistor should be connected between pin 8 and pin 10.

The analog input is connected between pin 13 and pin 9 for a 0 to +10V input range, between 14 and pin 9 for a 0 to +20V input range. The AD574A easily accommodates an input signal beyond the supplies. For the 10 volt span input, the LSB has a nominal value of 2.44mV; for the 20 volt span, 4.88mV. If a 10.24V range is desired (nominal 2.5mV/bit), the gain trimmer (R2) should be replaced by a 50Ω resistor, and a 200Ω trimmer inserted in series with the analog input to pin 13 for a full-scale range of 20.48V (5mV/bit), use a 500Ω trimmer into pin 14. The gain trim described below is now done with these trimmers. The nominal input impedance into pin 13 is 5kΩ, and 10kΩ into pin 14.

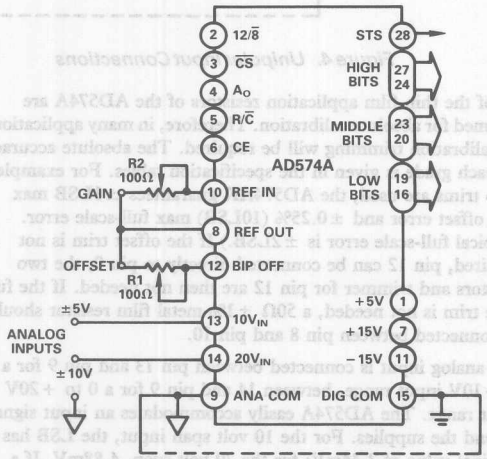
The AD574A is intended to have a nominal 1/2LSB offset so that the exact analog input for a given code will be in the middle of that code (halfway between the transitions to the codes above and below it). Thus, the first transition (from 0000 0000 0000 to 0000 0000 0001) will occur for an input level of +1/2LSB (1.22mV for 10V range).

If pin 12 is connected to pin 9, the unit will behave in this manner, within specifications. If the offset trim (R1) is used, it should be trimmed as above, although a different offset can be set for a particular system requirement. This circuit will give approximately ±15mV of offset trim range.

The full-scale trim is done by applying a signal 1 1/2LSB below the nominal full scale (9.9963 for a 10V range). Trim R2 to give the last transition (1111 1111 1110 to 1111 1111 1111).

BIPOLAR OPERATION

The connections for bipolar ranges are shown in Figure 5. Again, as for the unipolar ranges, if the offset and gain specifications are sufficient, one or both of the trimmers shown can be replaced by a 50Ω ±1% fixed resistor. Bipolar calibration is similar to unipolar calibration. First, a signal ½LSB above negative full scale (−4.9988V for the ±5V range) is applied and R1 is trimmed to give the first transition (0000 0000 0000 to 0000 0000 0001). Then a signal 1½LSB below positive full scale (+4.9963V for the ±5V range) is applied and R2 trimmed to give the last transition (1111 1111 1110 to 1111 1111 1111).



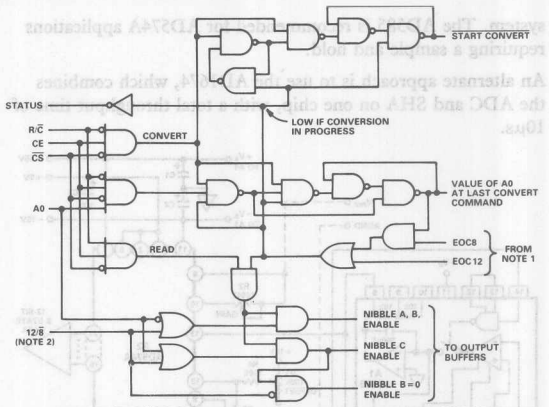


Figure 5. Bipolar Input Connections

CONTROL LOGIC

The AD574A contains on-chip logic to provide conversion initiation and data read operations from signals commonly available in microprocessor systems. Figure 6 shows the internal logic circuitry of the AD574A.

The control signals CE, $\overline{CS}$, and R/$\overline{C}$ control the operation of the converter. The state of R/$\overline{C}$ when CE and $\overline{CS}$ are both asserted determines whether a data read (R/$\overline{C}$ = 1) or a convert (R/$\overline{C}$ = 0) is in progress. The register control inputs A_0 and 12/$\overline{8}$ control conversion length and data format. The A_0 line is usually tied to the least significant bit of the address bus. If a conversion is started with A_0 low, a full 12-bit conversion cycle is initiated. If

NOTE 1: WHEN START CONVERT GOES LOW, THE EOC (END OF CONVERSION) SIGNALS GO LOW. EOC8 RETURNS HIGH AFTER AN 8-BIT CONVERSION CYCLE IS COMPLETE, AND EOC12 RETURNS HIGH WHEN ALL 12 BITS HAVE BEEN CONVERTED. THE EOC SIGNALS PREVENT DATA FROM BEING READ DURING CONVERSIONS.

NOTE 2: 12/$\overline{8}$ IS NOT A TTL-COMPATIBLE INPUT AND SHOULD ALWAYS BE WIRED DIRECTLY TO V_{LOGIC} OR DIGITAL COMMON.

Figure 6. AD574A Control Logic

A_0 is high during a convert start, a shorter 8-bit conversion cycle results. During data read operations, A_0 determines whether the three-state buffers containing the 8 MSBs of the conversion result (A_0 = 0) or the 4 LSBs (A_0 = 1) are enabled. The 12/$\overline{8}$ pin determines whether the output data is to be organized as two 8-bit words (12/$\overline{8}$ tied to DIGITAL COMMON) or a single 12-bit word (12/$\overline{8}$ tied to V_{LOGIC}). The 12/$\overline{8}$ pin is not TTL-compatible and must be hard-wired to either V_{LOGIC} or DIGITAL COMMON. In the 8-bit mode, the byte addressed when A_0 is high contains the 4 LSBs from the conversion followed by four trailing zeroes. This organization allows the data lines to be overlapped for direct interface to 8-bit buses without the need for external three-state buffers.

It is not recommended that A_0 change state during a data read operation. Asymmetrical enable and disable times of the three-state buffers could cause internal bus contention resulting in potential damage to the AD574A.

An output signal, STS, indicates the status of the converter. STS goes high at the beginning of a conversion and returns low when the conversion cycle is complete.

CE	$\overline{CS}$	R/$\overline{C}$	12/$\overline{8}$	A_0	Operation
0	X	X	X	X	None
X	1	X	X	X	None
1	0	0	X	0	Initiate 12-Bit Conversion
1	0	0	X	1	Initiate 8-Bit Conversion
1	0	1	Pin 1	X	Enable 12-Bit Parallel Output
1	0	1	Pin 15	0	Enable 8 Most Significant Bits
1	0	1	Pin 15	1	Enable 4LSBs +4 Trailing Zeroes

Table I. AD574A Truth Table

TIMING

The AD574A is easily interfaced to a wide variety of microprocessors and other digital systems. The following discussion of the timing requirements of the AD574A control signals should provide the system designer with useful insight into the operation of the device.

CONVERT START TIMING – FULL CONTROL MODE

Symbol	Parameter	Min	Typ	Max	Units
t_{DSC}	STS Delay from CE			400	ns
t_{HEC}	CE Pulse Width	300			ns
t_{SSC}	$\overline{CS}$ to CE Setup	300			ns
t_{HSC}	$\overline{CS}$ Low During CE High	200			ns
t_{SRC}	R/$\overline{C}$ to CE Setup	250			ns
t_{HRC}	R/$\overline{C}$ Low During CE High	200			ns
t_{SAC}	A_O to CE Setup	0			ns
t_{HAC}	A_O Valid During CE High	300			ns
t_C	Conversion Time				
	8-Bit Cycle	10		24	µs
	12-Bit Cycle	15		35	µs

Figure 7 shows a complete timing diagram for the AD574A convert start operation. R/$\overline{C}$ should be low before both CE and $\overline{CS}$ are asserted; if R/$\overline{C}$ is high, a read operation will momentarily occur, possibly resulting in system bus contention. Either CE or $\overline{CS}$ may be used to initiate a conversion; however, use of CE is recommended since it includes one less propagation delay than $\overline{CS}$ and is the faster input. In Figure 7, CE is used to initiate the conversion.

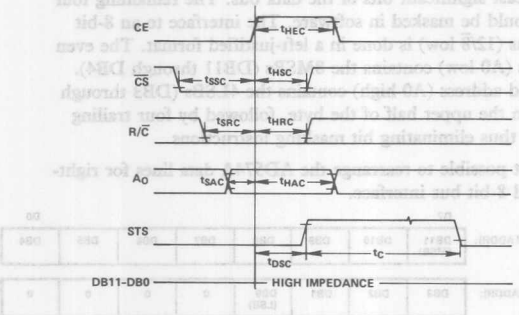

Figure 7. Convert Start Timing

Once a conversion is started and the STS line goes high, convert start commands will be ignored until the conversion cycle is complete. The output data buffers cannot be enabled during conversion.

Figure 8 shows the timing for data read operations. During data read operations, access time is measured from the point where CE and R/$\overline{C}$ both are high (assuming $\overline{CS}$ is already low). If $\overline{CS}$ is used to enable the device, access time is extended by 100ns.

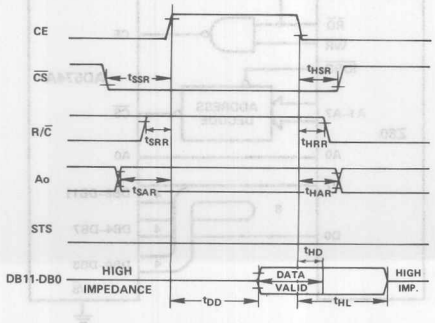

Figure 8. Read Cycle Timing

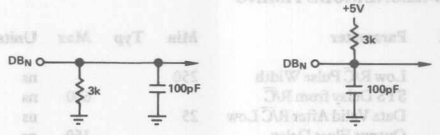
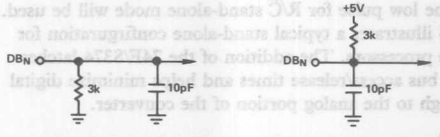


In the 8-bit bus interface mode (12/$\overline{8}$ input wired to DIGITAL COMMON), the address bit, A_O, must be stable at least 150ns prior to $\overline{CE}$ going high and must remain stable during the entire read cycle. If A_O is allowed to change, damage to the AD574A output buffers may result.

READ TIMING – FULL CONTROL MODE

Symbol	Parameter	Min	Typ	Max	Units
t_{DD}[1]	Access Time (from CE)			200	ns
t_{HD}	Data Valid after CE Low	25			ns
t_{HL}[2]	Output Float Delay			100	ns
t_{SSR}	$\overline{CS}$ to CE Setup	150			ns
t_{SRR}	R/$\overline{C}$ to CE Setup	0			ns
t_{SAR}	A_O to CE Setup	150			ns
t_{HSR}	$\overline{CS}$ Valid After CE Low	50			ns
t_{HRR}	R/$\overline{C}$ High After CE Low	0			ns
t_{HAR}	A_O Valid After CE low	50			ns



[1] t_{DD} is measured with the load circuit of Figure 9 and defined as the time required for an output to cross 0.4V or 2.4V.

[2] t_{HL} is defined as the time required for the data lines to change 0.5V when loaded with the circuit of Figure 10.

Figure 10. Load Circuit for Output Float Delay Test

"STAND-ALONE" OPERATION

The AD574A can be used in a "stand-alone" mode, which is useful in systems with dedicated input ports available and thus not requiring full bus interface capability.

In this mode, CE and 12/$\overline{8}$ are wired high, $\overline{CS}$ and A_O are wired low, and conversion is controlled by R/$\overline{C}$. The three-state buffers are enabled when R/$\overline{C}$ is high and a conversion starts when R/$\overline{C}$ goes low. This allows two possible control signals – a high pulse or a low pulse. Operation with a low pulse is shown in Figure 11. In this case, the outputs are forced into the high-impedance state in response to the falling edge of R/$\overline{C}$ and return

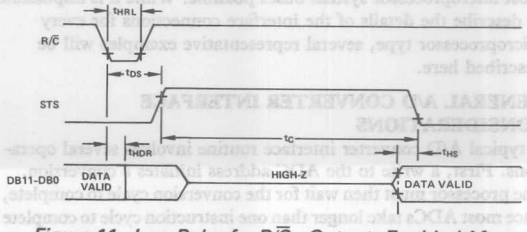

Figure 11. Low Pulse for R/$\overline{C}$ – Outputs Enabled After Conversion

to valid logic levels after the conversion cycle is completed. The STS line goes high 600ns after R/$\overline{C}$ goes low and returns low 300ns after data is valid.

If conversion is initiated by a high pulse as shown in Figure 12, the data lines are enabled during the time when R/$\overline{C}$ is high. The falling edge of R/$\overline{C}$ starts the next conversion, and the data lines return to three-state (and remain three-state) until the next high pulse of R/$\overline{C}$.

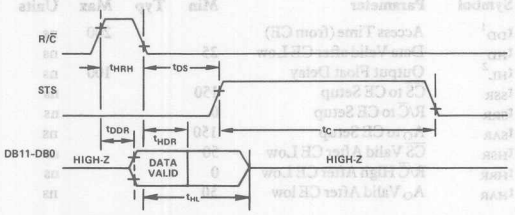

Figure 12. High Pulse for R/$\overline{C}$ – Outputs Enabled While R/$\overline{C}$ High, Otherwise High-Z

STAND-ALONE MODE TIMING

Symbol	Parameter	Min	Typ	Max	Units
t_{HRL}	Low R/$\overline{C}$ Pulse Width	250			ns
t_{DS}	STS Delay from R/$\overline{C}$			600	ns
t_{HDR}	Data Valid After R/$\overline{C}$ Low	25			ns
t_{HL}	Output Float Delay			150	ns
t_{HS}	STS Delay After Data Valid	300		1000	ns
t_{HRH}	High R/$\overline{C}$ Pulse Width	300			ns
t_{DDR}	Data Access Time			250	ns

Usually the low pulse for R/$\overline{C}$ stand-alone mode will be used. Figure 13 illustrates a typical stand-alone confirguration for 8086 type processors. The addition of the 74F/S374 latches improves bus access/release times and helps minimize digital feedthrough to the analog portion of the converter.

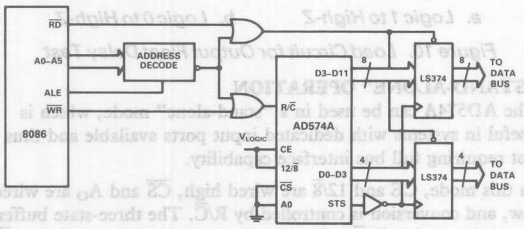

Figure 13. 8086 Stand-Alone Configuration

INTERFACING THE AD574A TO MICROPROCESSORS

The control logic of the AD574A makes direct connection to most microprocessor system buses possible. While it is impossible to describe the details of the interface connections for every microprocessor type, several representative examples will be described here.

GENERAL A/D CONVERTER INTERFACE CONSIDERATIONS

A typical A/D converter interface routine involves several operations. First, a write to the ADC address initiates a conversion. The processor must then wait for the conversion cycle to complete, since most ADCs take longer than one instruction cycle to complete a conversion. Valid data can, of course, only be read after the conversion is complete. The AD574A provides an output signal (STS) which indicates when a conversion is in progress. This signal can be polled by the processor by reading it through an external three-state buffer (or other input port). The STS signal can also be used to generate an interrupt upon completion of conversion, if the system timing requirements are critical (bear in mind that the maximum conversion time of the AD574A is only 35 microseconds) and the processor has other tasks to perform during the ADC conversion cycle. Another possible time-out method is to assume that the ADC will take 35 microseconds to convert, and insert a sufficient number of "do-nothing" instructions to ensure that 35 microseconds of processor time is consumed.

Once it is established that the conversion is finished, the data can be read. In the case of an ADC of 8-bit resolution (or less), a single data read operation is sufficient. In the case of converters with more data bits than are available on the bus, a choice of data formats is required, and multiple read operations are needed. The AD574A includes internal logic to permit direct interface to 8-bit or 16-bit data buses, selected by connection of the 12/$\overline{8}$ input. In 16-bit bus applications (12/$\overline{8}$ high) the data lines (DB11 through DB0) may be connected to either the 12 most significant or 12 least significant bits of the data bus. The remaining four bits should be masked in software. The interface to an 8-bit data bus (12/$\overline{8}$ low) is done in a left-justified format. The even address (A0 low) contains the 8MSBs (DB11 through DB4). The odd address (A0 high) contains the 4LSBs (DB3 through DB0) in the upper half of the byte, followed by four trailing zeroes, thus eliminating bit masking instructions.

It is not possible to rearrange the AD574A data lines for right-justified 8-bit bus interface.

	D7							D0
XXX0 (EVEN ADDR):	DB11 (MSB)	DB10	DB9	DB8	DB7	DB6	DB5	DB4
XXX1 (ODD ADDR):	DB3	DB2	DB1	DB0 (LSB)	0	0	0	0

Figure 14. AD574A Data Format for 8-Bit Bus

SPECIFIC PROCESSOR INTERFACE EXAMPLES

Z-80 System Interface

The AD574A may be interfaced to the Z-80 processor in an I/O or memory mapped configuration. Figure 15 illustrates an I/O mapped configuration. The Z-80 uses address lines A0-A7 to decode the I/O port address.

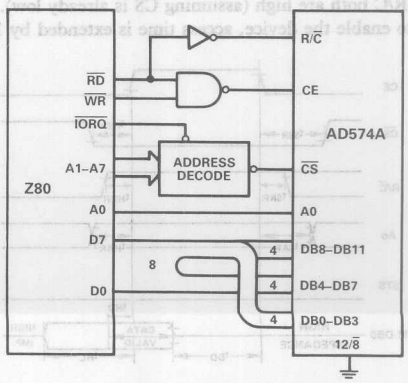

Figure 15. Z80–AD574A Interface

An interesting feature of the Z-80 is that during I/O operations a single wait state is automatically inserted, allowing the AD574A to be used with Z-80 processors having clock speeds up to 4MHz. For applications faster than 4MHz use the wait state generator in Figure 16. In a memory mapped configuration the AD574A may be interfaced to Z-80 processors with clock speeds of up to 2.5MHz.

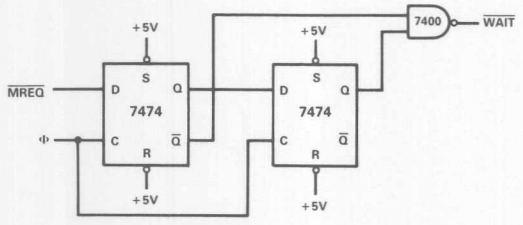

Figure 16. Wait State Generator

IBM PC Interface

The AD574A appears in Figure 17 interfaced to the 4MHz 8088 processor of an IBM PC. Since the device resides in I/O space, its address is decoded from only the lower ten address lines and must be gated with AEN (active low) to mask out internal DMA cycles which use the same I/O address space. This active low signal is applied to $\overline{CS}$. $\overline{IOR}$ and $\overline{IOW}$ are used to initiate the conversion and read, and are gated together to drive the chip enable, CE. Because the data bus width is limited to 8 bits, the AD574A data resides in two adjacent addresses selected by A0.

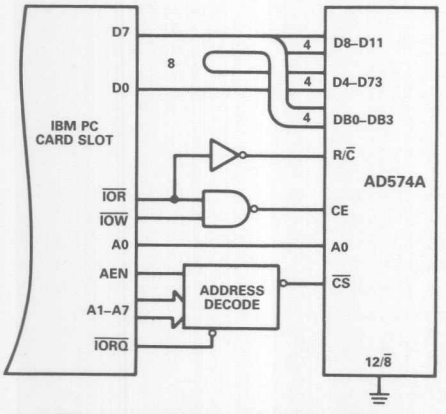

Figure 17. IBM PC – AD574A Interface

Note: Due to the large number of of options that may be installed in the PC, the I/O bus loading should be limited to one Schottky TTL load. Therefore, a buffer/driver should be used when interfacing more than two AD574As to the I/O bus.

8086 Interface

The data mode select pin (12/$\overline{8}$) of the AD574A should be connected to V_{LOGIC} to provide a 12-bit data output. To prevent possible bus contention, a demultiplexed and buffered address/data bus is recommended. In the cases where the 8-bit short conversion cycle is not used, A0 should be tied to digital common. Figure 18 shows a typical 8086 configuration.

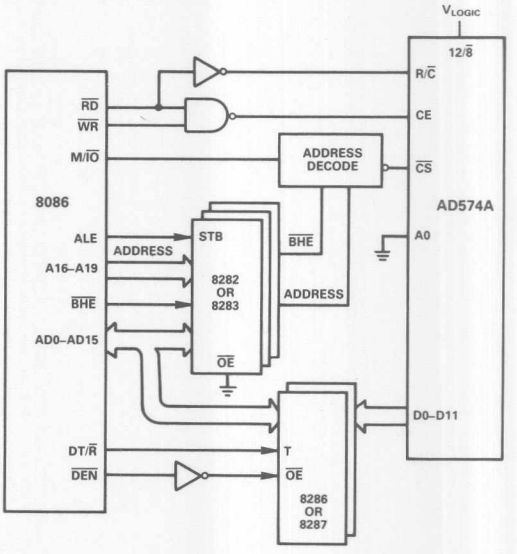

Figure 18. 8086 – AD574A with Buffered Bus Interface

For clock speeds greater than 4MHz wait state insertion similar to Figure 16 is recommended to ensure sufficient CE and R/$\overline{C}$ pulse duration.

The AD574A can also be interfaced in a stand-alone mode (see Figure 13). A low-going pulse derived from the 8086's $\overline{WR}$ signal logically ORed with a low address decode starts the conversion. At the end of the conversion, STS clocks the data into the three-state latches.

68000 Interface

The AD574, when configured in the stand-alone mode, will easily interface to the 4MHz version of the 68000 microprocessor. The 68000 R/$\overline{W}$ signal combined with a low address decode initiates conversion. The $\overline{UDS}$ or $\overline{LDS}$ signal, with the decoded address, generates the $\overline{DTACK}$ input to the processor, latching in the AD574A's data. Figure 19 illustrates this configuration.

with Serial Output

AD575*

FEATURES

Complete Serial Output 10-Bit A/D Converter with Reference, Clock and Comparator
30μs Conversion
No Missing Codes Over Temperature
Operates on +5V and −12V to −15V Supplies
Low Cost Monolithic Construction
Internal or External Clock
Triggered or Continuous Conversions
Short Cycle Capability

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD575 is a complete 10-bit successive-approximation analog-to-digital converter consisting of a DAC, voltage reference, clock, comparator, successive approximation register (SAR) and serial interface on a single chip. No additional components are required to perform a full-accuracy 10-bit conversion in 30μs.

The AD575 incorporates the most advanced integrated circuit design and processing technology available. The successive approximation function is implemented with I^2L (integrated injection logic). Laser trimming of the SiCr thin-film resistor ladder network at the wafer stage insures high accuracy, which is maintained with a temperature-compensated sub-surface zener reference.

Operating on supplies of +5V and −12V to −15V, the AD575 will accept full scale analog inputs of 0V to +10V, 0V to +20V, −5V to +5V or −10V to +10V. The rising edge of a positive pulse on the CONVERT line initiates the conversion cycle. Eleven pulses will appear at the CLOCK OUTPUT pin with data valid on the falling edges of the clock waveform. The data is presented serially beginning with the MSB which is valid on the falling edge of the second clock pulse. The part may be programmed to perform 8-bit conversions or short cycled to 2-, 4-, 6- or 8-bit word lengths. $\overline{EOC}$ indicates that conversion is complete. The AD575 may be synchronized to an external clock if desired.

The AD575 is available in two versions for the 0 to +70°C temperature range, the AD575J and AD575K; packaging is a 14-pin plstic DIP.

PRODUCT HIGHLIGHTS

1. The AD575 is a complete 10-bit A/D converter. No external active components or control signals are required to perform a conversion.
2. The serial output of the AD575 allows a wide range of microprocessor interfacing and data transmission possibilities.
3. The device offers true 10-bit relative accuracy and exhibits no missing codes over its entire operating temperature range.
4. The AD575 adapts to unipolar or bipolar analog inputs by grounding or opening a single pin.
5. Performance is guaranteed with +5V and −12V or −15V supplies.
6. The AD575 can be synchronized to an external clock.
7. Conversions can be initiated externally or internally.
8. The AD575 can be short-cycled to 8 bits by pin programming.
9. The Short Cycle and Terminate feature allows the user to program conversions of 2, 4, 6 or 8 bits.

***Protected by U.S. Patent Nos. 3,940,760; 4,400,689; and 4,400,690.**

NOTES

[1]Gain Error is specified with a 15Ω resistor in series with the 10V input (Pins 1 and 2 tied together) or a 30Ω resistor in series with the 20V input (Pin 1 with Pin 2 tied to analog common). Gain Error is guaranteed trimmable to zero (see text).

[2]The gain drift is calculated from gain measurements at the extremes of the temperature range under consideration.

[3]Relative Accuracy, also referred to as Integral Linearity, is defined as the deviation of the code transition points from the ideal transfer points on a straight line from zero to full-scale. It is also a measure of the error which remains when offset and full scale errors are trimmed to zero in an application.

[4]Measured at full scale.

[5]These specifications apply to the CONV, XCL, and $\overline{SCAT}$ inputs. $\overline{CLI}$ is hardwired to DGND or $+V_S$ in most applications. Typically I_{INH} = +350μA and I_{INL} = 120μA for the $\overline{CLI}$ input.

Specifications shown in boldface are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS

2

FUNCTIONAL DESCRIPTION

A block diagram of the AD575 is shown in Figure 1. A conversion is initiated by a positive pulse on the CONVERT line. $\overline{EOC}$ goes high within 150ns indicating that a conversion has started. The internal 10-bit current-output DAC is sequenced by the successive approximation register (SAR) from most significant bit to least significant bit to provide an output current which accurately balances the input signal current through the 10kΩ input resistor(s). The comparator determines whether the addition of each successively-weighted bit current causes the DAC current to be higher or lower than the input current. If the sum is less the bit is left on ($\overline{DO}$ set low). If the sum is more, the bit is turned off ($\overline{DO}$ set high). The result of each bit decision is passed to $\overline{DO}$ on the rising edge of CO.

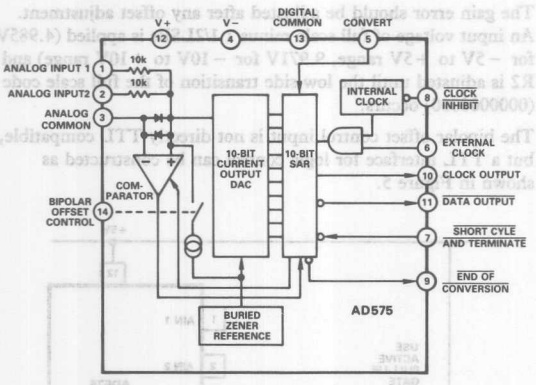

Figure 1. AD575 Functional Block Diagram

After all bits have been tested, the DAC output current will match the input signal current to within 0.05% (1/2LSB). $\overline{EOC}$ returns low after the final bit decision to indicate that the AD575 has been reset and is ready to perform a new conversion. The output data stream can be synchronized to an external clock using the XCL input and short cycled to any desired word length using the $\overline{SCAT}$ line.

The AD575 contains all the active components required to perform a complete A/D conversion. Thus, for many applications, all that is necessary is to connect the power supplies (+5V and −12V or −15V), and the analog input. The pinout is shown in Figure 2.

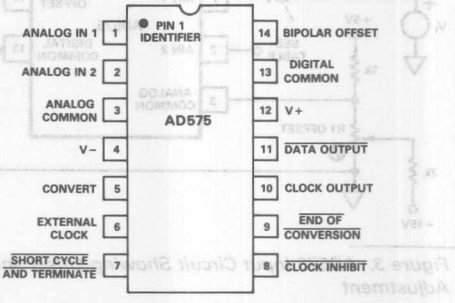

Figure 2. AD575 Pin Connections

ANALOG INPUT CONNECTIONS

The AD575 can be configured for unipolar or bipolar operation on 10V span or 20V span input signals. The appropriate input range is selected by connecting pins 2 and 14 according to the table of Figure 3.

The AD575's low offset and gain errors (shown in the Specifications) are adequate for most applications. For these cases, a fixed gain resistor (R2 in Figure 3) is the only external component, in addition to any power supply decoupling that may be required. Pins 3 and 13 should be connected directly together.

Figure 3 shows a trimming circuit that can be used to adjust the offset to zero, using the appropriate value of the R1 potentiometer as shown in the table. If gain trim is required, R2 should also be replaced by the appropriate potentiometer as shown in the table.

ANALOG INPUT RANGE	CONNECTIONS PIN 2	CONNECTIONS PIN 14	COMPONENTS R1 (OFFSET)	COMPONENTS R2 (GAIN)
0V TO +10V	PIN 1	PIN 13	10Ω	15Ω FIXED OR 50Ω POT
0V TO +20V	PIN 3	PIN 13	20Ω	30Ω FIXED OR 100Ω POT
−5V TO +5V	PIN 1	OPEN	10Ω	15Ω FIXED OR 50Ω POT
−10V TO +10V	PIN 3	OPEN	20Ω	30Ω FIXED OR 100Ω POT

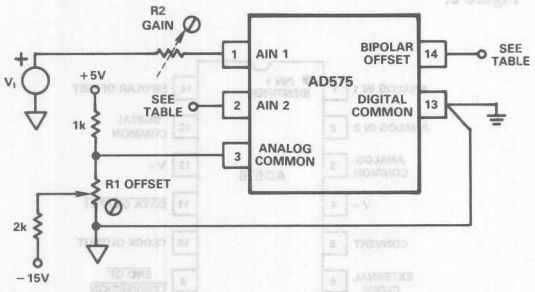

Figure 3. AD575 Input Circuit Showing Offset and Gain Adjustment

UNIPOLAR MODE OPERATION

In unipolar mode, the nominal location of the low side transition of the first code (1111111110) occurs at an input voltage of +1LSB (10mV for the 10V span, 20mV for the 20V span). The offset error of the AD575 can be trimmed out, if required, by applying an input voltage of +1LSB to the analog input and adjusting R1 until the low side transition of the first code occurs.

If the Gain Error needs to be trimmed, the gain resistor should be replaced with a potentiometer according to Figure 3. The nominal location of the low side transition of the full scale code (0000000000) in unipolar mode is full scale minus 1LSB (9.99V for 10V span, 19.98V for 20V span). Once the offset has been adjusted, the full scale range can be set by adjusting the gain potentiometer.

BIPOLAR CONNECTION

If the bipolar offset control (pin 14) is left open, the AD575 will accept bipolar input voltages with 0V as the nominal bipolar zero point. The input voltage corresponding to the low side transition of the mid-scale code (0111111111) is −1/2LSB (−5mV for 10V spans and −10mV for 20V spans). The nominal location of the code transitions are therefore offset by 1/2LSB as shown in Figure 4. This offset may be adjusted using the trim scheme shown in Figure 3 with a 1.2kΩ resistor in place of the 1kΩ resistor shown.

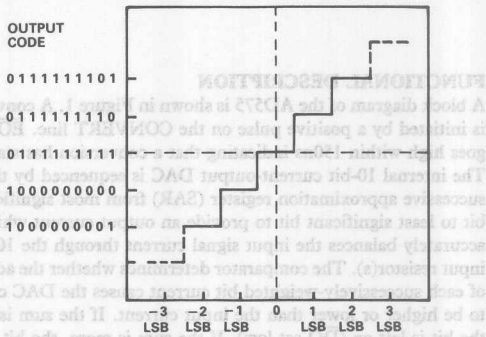

Figure 4. AD575 Transfer Characteristic (Bipolar Operation)

The gain error should be adjusted after any offset adjustment. An input voltage of full scale minus 1 1/2LSBs is applied (4.985V for −5V to +5V range, 9.971V for −10V to +10V range) and R2 is adjusted until the low-side transition of the full scale code (0000000000) occurs.

The bipolar offset control input is not directly TTL compatible, but a TTL interface for logic control can be constructed as shown in Figure 5.

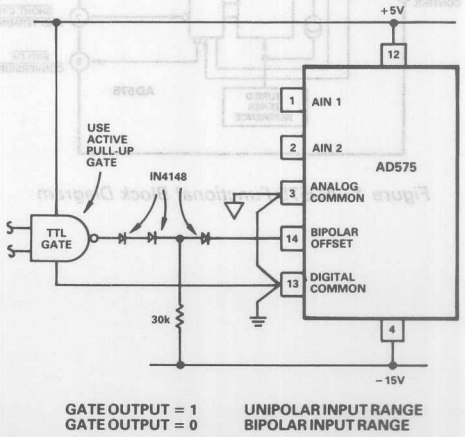

Figure 5. Bipolar Offset Controlled by Logic Gate

CONTROL AND TIMING OF THE AD575

The AD575 has a flexible control architecture which supports several operating modes. It can provide its own clock or it can be synchronized to an external clock. Conversions can be initiated externally, or the part can perform continuous conversions yielding a stream of output data. In addition, the AD575 can be short-cycled to any of several convenient data word lengths to tailor the output to the specific input requirements of the system. Figure 6 shows the control logic diagram of the AD575. The four inputs which control the operation of the AD575 are CONV (convert), $\overline{CLI}$ (clock inhibit), XCL (external clock), and $\overline{SCAT}$ (short cycle and terminate). Three outputs are provided: $\overline{DO}$ (Data Out), CO (Clock Out), and $\overline{EOC}$ (End of Conversion).

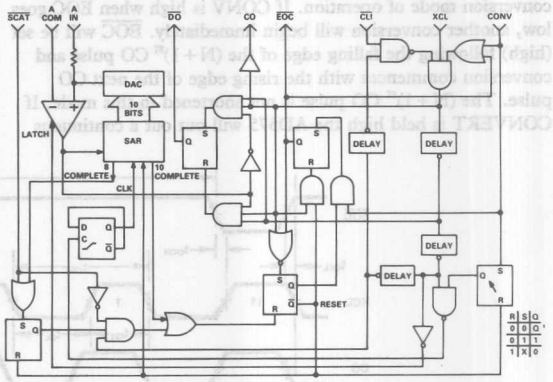

Figure 6. AD575 Control Logic Diagram

EXTERNALLY INITIATED CONVERSIONS

Figure 7 is the timing diagram which illustrates the operation of the AD575 with an externally applied convert signal. Conversions are initiated by a positive-going pulse applied to the CONV (convert) input. This pulse should be at least 250ns wide and should return low before $\overline{EOC}$ returns low to prevent the initiation of a second conversion. If the internal clock is used, the clock will start on the rising edge of the convert start pulse. If an external clock is used, the falling edge of the clock must occur no earlier than 900ns following the rising edge of the convert command.

INTERNAL CLOCK MODE

The AD575 can be configured for internal clock operation by tying $\overline{CLI}$ and XCL to +5V. CO (clock output) provides the necessary synchronizing information in this mode. Data is transferred to $\overline{DO}$ on the rising clock edge and is stable on the falling edge. The duty cycle of the CO waveform in this mode will be in the range of 30% to 70%.

EXTERNAL CLOCK MODE

When $\overline{CLI}$ is connected to digital common, an external clock can be applied to XCL. The external clock should have a maximum frequency of 450kHz with a minimum of 900ns in the high or low phase. Arbitrarily slow clocks may be used as long as these minimum high and low periods are observed. Conversion time will increase as clock frequency decreases. Each data bit will be stable within 150ns of the rising edge of the associated external clock pulse and will remain stable until the rising edge of the subsequent clock pulse. Data is guaranteed to be stable on the falling edge of the clock pulse.

The state of the $\overline{DO}$ output during the first clock period is undefined but it is stable until the rising edge of the second clock period. The MSB appears at $\overline{DO}$ during the second clock period. The subsequent data bits are then clocked out until the Nth bit or LSB is clocked out on the $(N+1)^{th}$ clock pulse. $\overline{EOC}$ returns low within 150ns of the rising edge of this final clock pulse. In internal clock mode, the output clock pulse associated with the LSB is shorter than the others but the LSB is guaranteed to be stable on the falling edge of this pulse. The LSB will remain stable until a new conversion is initiated. The value of N will be 10 unless the conversion has been short cycled (see "short cycle and terminate" text).

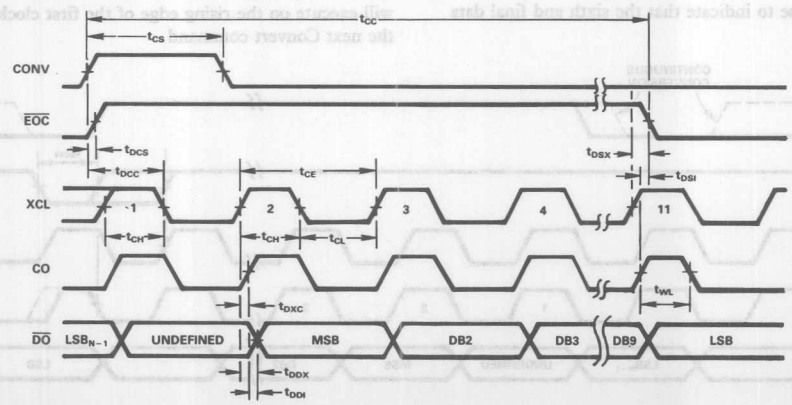

Figure 7. Externally Initiated Conversions

CONTINUOUS CONVERSIONS

Figure 8 is the timing diagram associated with the continuous conversion mode of operation. If CONV is high when $\overline{EOC}$ goes low, another conversion will begin immediately. $\overline{EOC}$ will be set (high) following the falling edge of the $(N+1)^{st}$ CO pulse and conversion commences with the rising edge of the next CO pulse. The $(N+1)^{st}$ CO pulse is not shortened in this mode. If CONVERT is held high the AD575 will put out a continuous stream of conversions, punctuated by $\overline{EOC}$ which will mark the last clock pulse of a conversion. $\overline{EOC}$ will remain low until the falling edge of CO, the output clock, in this mode. Therefore, the rising edge of $\overline{EOC}$ may be used to signal that conversion is complete and that data is transferred. This sequence is useful for initiating parallel dumps from a serially loaded shift register.

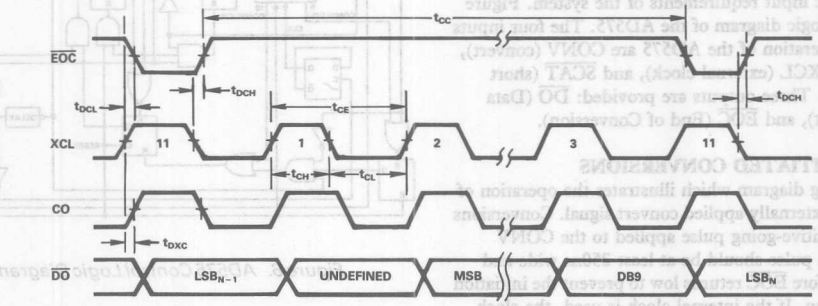

Figure 8. Continuous Conversion Mode (CONV. Held High)

SHORT CYCLE AND TERMINATE

For normal 10-bit operation, the Short Cycle and Terminate ($\overline{SCAT}$) line should be tied high. If 8-bit conversions are required, $\overline{SCAT}$ should be tied low. In this mode, $\overline{EOC}$ will go low after the rising edge of the ninth clock pulse to indicate that the eighth and final data bit is valid. This mode is useful when parallel loads to 8-bit data buses are desired since it avoids the complication of suppressing the 9th and 10th data bits.

Conversions of 2, 4, 6 or 8 bits can be performed by pulling $\overline{SCAT}$ low during the negative clock phase prior to the positive clock associated with the desired LSB. Figure 9 illustrates the timing associated with this mode of operation. For example, to terminate the conversion after six data bits, $\overline{SCAT}$ should be driven low during the negative clock phase following the sixth clock pulse. $\overline{EOC}$ will then go low following the rising edge of the seventh clock pulse to indicate that the sixth and final data bit is valid.

This terminate feature can also be used to program conversions of 1, 3, 5, 7 or 9 bits. However, the conversion immediately following a conversion of an odd number of data bits will be spurious. All subsequent conversions will be normal until the conversion following another odd data word length conversion.

The negative edge of the $\overline{SCAT}$ signal should always occur during the negative phase of a clock cycle and it should be held low for a minimum of 900ns. $\overline{SCAT}$ may be held low into the next conversion but it must be restored high at least one clock cycle prior to being used to terminate a conversion. If $\overline{SCAT}$ is not restored high prior to the eighth clock pulse, $\overline{EOC}$ will go low and an 8-bit short cycle will occur. Care should be taken not to pulse $\overline{SCAT}$ from high to low between conversions (when $\overline{EOC}$ is low). This would initiate a terminate sequence which will execute on the rising edge of the first clock pulse following the next Convert command.

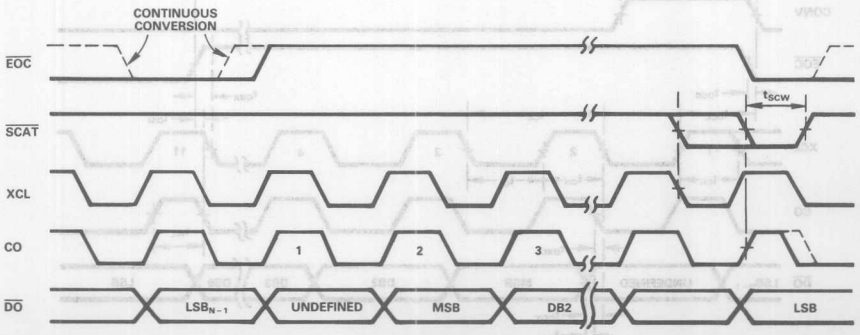

Figure 9. Short Cycle and Terminate Operation

Table I. AD575 Timing Specifications

SAMPLE-HOLD AMPLIFIER CONNECTION TO THE AD575

Many data acquisition systems for digitizing rapidly changing signals require a sample-hold amplifier (SHA) in front of the A/D converter. A SHA can be used to accurately define the exact point in time at which the signal is sampled. A SHA can also serve as a high input-impedance buffer for the AD575.

Figure 10 shows the AD575 connected to the AD585 monolithic SHA. In this configuration, the AD585 will acquire a 10V signal in less than 2µs and droop less than 1mV/ms using the on-chip hold capacitor.

$\overline{EOC}$ goes high after the conversion is initiated to indicate that a conversion is underway. In Figure 10 it is also used to put the AD585 into the hold mode while the AD575 begins its conversion cycle. (The AD585 output settles to final value well in advance of the first comparator decision within the AD575.) $\overline{EOC}$ goes low when the conversion is complete placing the AD585 back in the sample mode.

Configured as shown in Figure 10, the next conversion can be initiated after a 2µs delay to allow for signal acquisition by the AD585.

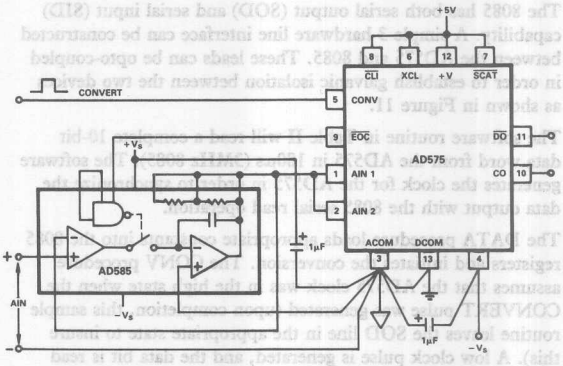

Figure 10. AD575 to AD585 Sample and Hold Interface

SUPPLY DECOUPLING AND LAYOUT

For proper operation, the AD575's power supplies should be free from high-frequency noise. The stability of the transfer function is especially sensitive to noise on the V− supply. Noise on the V+ supply can also propagate to the digital outputs.

If decoupling is required, tantalum capacitors are suggested. Best results will be obtained if the capacitors are connected directly to the appropriate pins of the AD575. Decoupling capacitors for V− should be connected between pin 4 and Analog Common (pin 3). Decoupling capacitors for V+ should be connected between pin 12 and Digital Common (pin 13).

Good circuit layout practice suggests that the AD575 and its associated analog input circuitry be kept separate from system logic circuitry to avoid unwanted interactions.

GROUNDING CONSIDERATIONS

The AD575 provides separate Analog and Digital Common connections. The circuit will operate properly with as much as ±200mV of common-mode voltage between the two commons. The absolute maximum voltage rating between the two commons is ±1V. A parallel pair of back-to-back protection diodes should be connected between the commons if they are not connected locally.

In normal operation, the Analog Common terminal may generate transient currents of up to 2mA during a conversion. In addition, a static current of about 2mA will flow into Analog Common in the unipolar mode after a conversion is complete. The Analog Common current will be modulated by the variations in input signal.

AD575 TO 8085 INTERFACE

The 8085 has both serial output (SOD) and serial input (SID) capability. A simple 3 hardware line interface can be constructed between the AD575 and 8085. These leads can be opto-coupled in order to establish galvanic isolation between the two devices as shown in Figure 11.

The software routine in Table II will read a complete 10-bit data word from the AD575 in 180μs (3MHz 8085). The software generates the clock for the AD575 in order to synchronize the data output with the 8085 serial read operation.

The DATA procedure loads appropriate constants into the 8085 registers and initiates the conversion. The CONV procedure assumes that the AD575 clock was in the high state when the CONVERT pulse was generated (upon completion, this sample routine leaves the SOD line in the appropriate state to insure this). A low clock pulse is generated, and the data bit is read into the MSB of the accumulator. The data bit is then shifted into the LSB of the temporary register (L), the clock is set high, and the procedure is repeated.

After the loop has executed three times, a logical AND is performed to set the first bit (the undefined bit) to zero, and the result is placed into the high byte (H) register. The loop counter is then reset, and the CONV procedure is executed 8 more times. Upon completion of the sample routine, 10 bits of right-justified data will reside in the HL register pair.

Note that the opto-isolators invert the clock and data lines. If these are not used (no inversion present), the constants in the D and E registers should be swapped, a CMA instruction should be inserted after the RIM instruction, and an inverter should be connected between the address decoder and the CONVERT pin. Also, the results of the first pass through the routine should be ignored following power up and reset cycles to insure that the AD575 has been reset.

LABEL	MNEMONIC	OPERAND	COMMENT
DATA	MVI	B,03	Set inner loop counter to 3
	MVI	C,02	Set outer loop counter to 2
	MVI	D,CO	Setup register D for clock low
	MVI	E,40	Setup register E for clock high
	MVI	H,10	AD575 address location
	MVI	L,00	Clear temp register
	MOV	M,B	Generate CONVERT pulse
CONV	MOV	A,D	Setup ACC for clock low
	SIM		Output clock low
	RIM		Read AD575 data bit into ACC
	RAL		Shift data bit into Carry
	MOV	A,L	Move temp to ACC
	RAL		Shift data bit from Carry to ACC
	MOV	L,A	Replace temp
	MOV	A,E	Setup ACC for clock high
	SIM		Output clock high
	DCR	B	Decrement inner loop counter
	JNZ	CONV	Repeat CONV until done
	DCR	C	Decrement outer loop counter
	JZ	DONE	Skip to DONE on 2nd pass
	MOV	A,L	Move temp to ACC
	ANI	03	Mask undefined bit
	MOV	H,A	Store temp in H register
	MVI	B,OB	Set inner loop counter to 8
	JMP	CONV	Repeat CONV for 8 LSBs
DONE	RET		10 bits of right-justified data now reside in HL; return

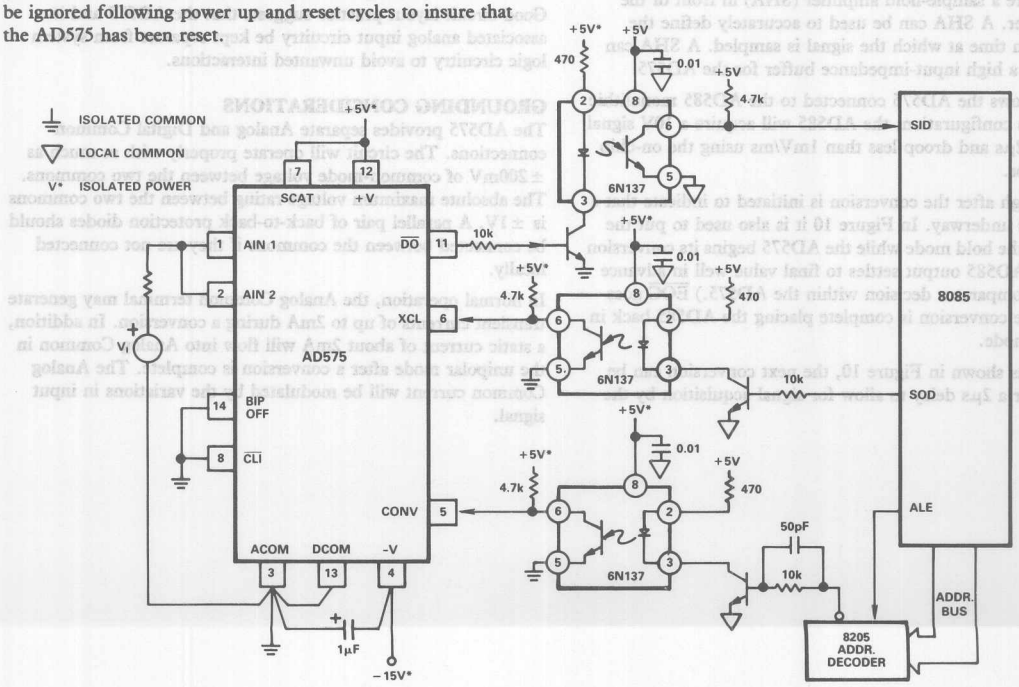

Figure 11. AD575 to 8085 Isolated Interface

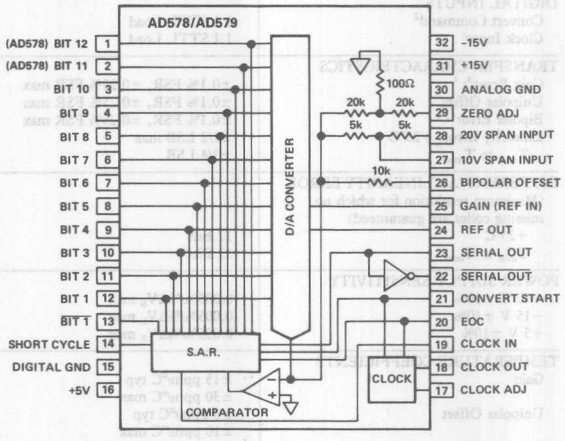
Very Fast, Complete 10- or 12-Bit A/D Converters

AD578/AD579

FEATURES



Performance

- Complete 12-Bit A/D Converter with Reference and Clock
- Fast Conversion: 3 μs (max)
- Buried Zener Reference for Long Term Stability and Low Gain T.C.: ±30 ppm/°C max (AD578)
  ±40 ppm/°C max (AD579)
- Max Nonlinearity: <±0.012%
- No Missing Codes Over Temperature
- Low Power: 555 mW (AD578); 775 mW (AD579)
- Available to MIL-STD-883

Versatility

- Positive-True Parallel or Serial Logic Outputs
- Short Cycle Capability
- Precision +10 V Reference for External Applications
- Adjustable Internal Clock
- "Z" Models for ±12 V Supplies

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD578 and AD579 are high speed 12-bit and 10-bit successive approximation analog-to-digital converters that include internal clock, reference, and comparator. Their hybrid design utilizes MSI digital and linear ICs in conjunction with a 12-bit or 10-bit monolithic, monotonic DAC to provide superior performance and versatility with IC size, price, and reliability.

Important performance characteristics of the AD578 include ±1/2 LSB_{12} linearity error maximum at +25°C, maximum gain tempco of ±30 ppm/°C, and maximum conversion time of 3 μs at a typical power dissipation of 555 mW. The 10-bit AD579 provides ±1/2 LSB_{10} maximum linearity error at 1.8 μs maximum, and 775 mW typical P_D.

Both the AD578 and AD579 include scaling resistors that provide analog input signal ranges of ±5 V, ±10 V, and 0 to +10 V. Both are contained in 32-pin ceramic side-brazed DIP packages, and are available with MIL-STD-883 Class B processing.

PRODUCT HIGHLIGHTS

1. Both are complete analog-to-digital converters. No external components are required to perform a conversion.
2. The fast conversion rates—3 μs for the AD578, and 1.8 μs for the AD579—make them ideal candidates for high speed data acquisition systems requiring high throughput.
3. The internal buried Zener reference is laser trimmed to high initial accuracy and low T.C. and is available externally.
4. Precision thin film scaling resistors on the DAC provide for excellent thermal tracking.
5. Short cycle and external clock capabilities are provided for applications requiring faster conversion speeds and/or lower resolution.

NOTES
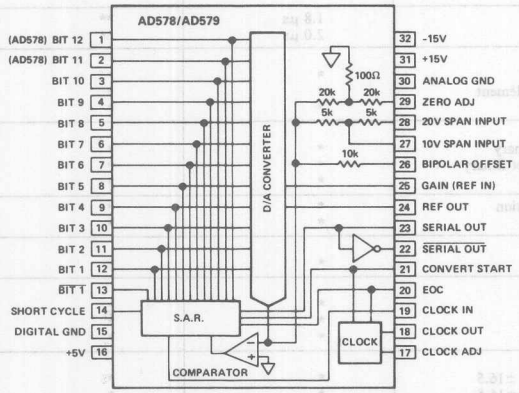
[1]For ±12 V operation "Z" Version, order AD578ZTD
[2]For outline information see Package Information section.

THEORY OF OPERATION

The AD578 is a complete pretrimmed 12-bit A/D converter which requires no external components to provide the successive-approximation analog-to-digital conversion function. A block diagram of the AD578 is shown in Figure 1.



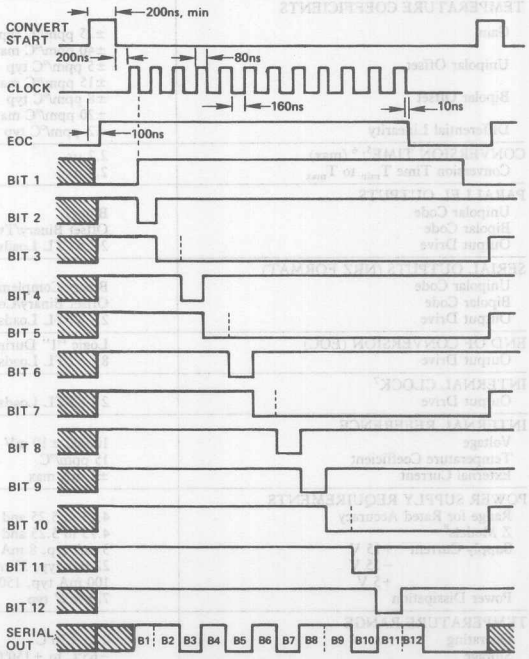


Figure 1. AD578/AD579 Functional Block Diagram and Pinout

When the control section is commanded to initiate a conversion it enables the clock and resets the successive-approximation register (SAR). The SAR, timed by the clock, sequences through the conversion cycle and returns an end-of-convert flag to the control section. The control section disables the clock and brings the output status flag low. The data bits are valid on the falling edge of the clock pulse starting with t_1 and ending with t_{12} (Figure 2), and accurately represent the input signal to within ±1/2 LSB.

CLOCK
INTERNAL: CONNECT CLOCK OUT (18) TO CLOCK IN (19)
EXTERNAL: CONNECT EXTERNAL CLOCK TO CLOCK IN (19)
CLOCK SHOULD BE AT LEAST 30% DUTY CYCLE WITH MINIMUM PERIOD, T_{MIN} OF 100ns.

NOTE
[1]THE RISING EDGE OF CONVERT START PULSE RESETS THE MSB TO ZERO, AND THE LSBs TO ONE. THE TRAILING EDGE INITIATES CONVERSION.

Figure 2a. AD578 3 µs Timing Diagram

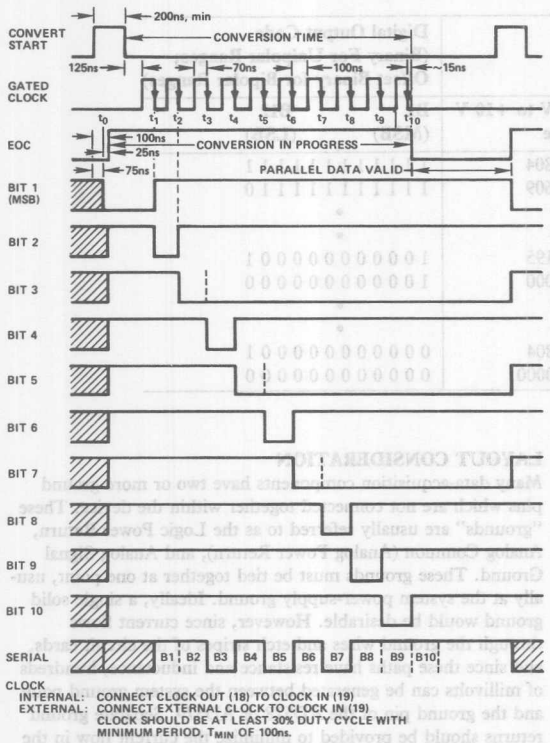

Figure 2b. AD579 Timing Diagram

The temperature-compensated buried Zener reference provides the primary voltage reference to the DAC and guarantees excellent stability with both time and temperature. The reference is trimmed to 10.00 volts ±1.0%, it is buffered and can supply up to 1.0 mA to an external load in addition to the current required to drive the reference input resistor (0.5 mA) and bipolar offset resistor (1 mA). The thin-film application resistors are trimmed to match the full scale output current of the DAC. There are two 5 kΩ input scaling resistors to allow either a 10 volt or 20 volt span. The 10 kΩ bipolar offset resistor is grounded for unipolar operation or connected to the 10 volt reference for bipolar operation.

UNIPOLAR CALIBRATION

The AD578/AD579 is intended to have a nominal 1/2 LSB offset so that the exact analog input for a given code will be in the middle of that code (halfway between the transitions to the codes above and below it). Thus, when properly calibrated, the first transition (from 0000 0000 0000 to 0000 0000 0001) will occur for an input level of +1/2 LSB.

If Pin 26 is connected to Pin 30, the unit will behave in this manner, within specifications. Refer to Table I, Table II, and Figure 3 for further clarification. If the offset trim (R1) is used, it should be trimmed as above, although a different offset can be set for a particular system requirement. This circuit will give approximately ±25 mV of offset trim range.

The full scale trim is done by applying a signal 1 1/2 LSB below the nominal full scale. Trim R2 to give the last transition (1111 1111 1110 to 1111 1111 1111).

BIPOLAR OPERATION

The connections for bipolar ranges are shown in Figure 4. Again, as for the unipolar ranges, if the offset and gain specifications are sufficient the 100 Ω trimmer shown can be replaced by a 50 Ω ±1% fixed resistor. The analog input is applied as for the unipolar ranges. Bipolar calibration is similar to unipolar calibration. First, a signal 1/2 LSB above negative full scale is applied, and R1 is trimmed to give the first transition (0000 0000 0000 to 0000 0000 0001). The a signal 1 1/2 LSB below positive full scale is applied and R2 trimmed to give the last transition (1111 1111 1110 to 1111 1111 1111).

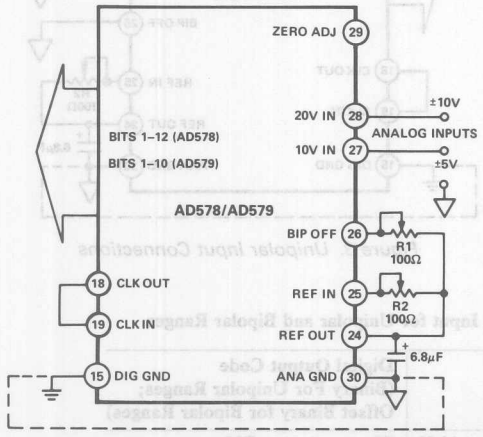

Figure 4. Bipolar Input Connections

LAYOUT CONSIDERATION

Many data-acquisition components have two or more ground pins which are not connected together within the device. These "grounds" are usually referred to as the Logic Power Return, Analog Common (Analog Power Return), and Analog Signal Ground. These grounds must be tied together at one point, usually at the system power-supply ground. Ideally, a single solid ground would be desirable. However, since current flows through the ground wires and etch stripes of the circuit cards, and since these paths have resistance and inductance, hundreds of millivolts can be generated between the system ground point and the ground pin of the AD578 or AD579. Separate ground returns should be provided to minimize the current flow in the path from sensitive points to the system ground point. In this way supply currents and logic-gate return currents are not summed into the same return path as analog signals where they would cause measurement errors.

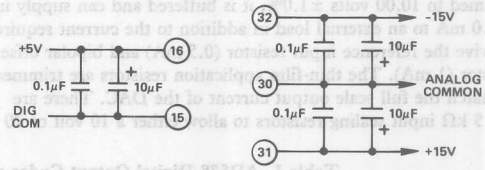

Figure 5. Basic Bypassing Practice

Each of the AD578 or AD579 supply terminals should be capacitively decoupled as close to the ADC as possible. A large value capacitor such as 10 μF in parallel with a 0.1 μF capacitor is usually sufficient. Analog supplies are bypassed to the Analog Power Return pin and the logic supply is bypassed to the Digital GND pin.

To minimize noise the reference output (Pin 24) should be decoupled by a 6.8 μF capacitor to Pin 30.

CLOCK RATE CONTROL

The internal clock is preset to a nominal conversion time of 5.6 μs (AD578) or 4.8 μs (AD579). It can be adjusted for either faster or slower conversion rates. For faster conversions connect the appropriate 1% resistor between Pins 17 and 18, and short Pin 18 to Pin 19. See Figure 6 or 7.

For slower conversions (AD578 only) connect a capacitor between Pins 15 and 17.

NOTE: No-Missing-Code operation is not guaranteed when operating in this mode if a particular grade's conversion speed specification is exceeded.

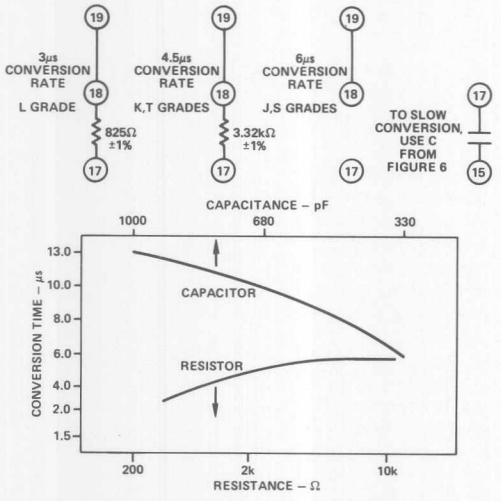

Figure 6. AD578 Conversion Times vs. R or C Values

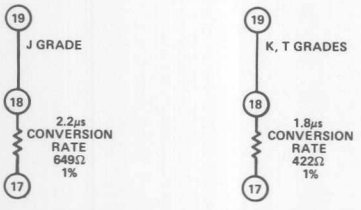

Figure 7. AD579 Clock Rate Control Connection

Short Cycle Input—A short cycle input, Pin 14, permits the timing cycle to be terminated after any number of desired bits has been converted, allowing shorter conversion times in applications not requiring the full 10-bit (AD579) or 12-bit (AD578) resolution. Short cycle pin connections and associated conversion times are summarized in Tables III and IV.

Table III. AD578 Short Cycle Connections

Resolution (Bits)	12	10	8
Connect Pin 14 to Pin	16	2	4
Conversion Speed (μs)	3	2.5	2

Table IV. AD579 Short Cycle Connections

Resolution (Bits)	10	8
Connect Pin 14 to Pin	2	4
Conversion Speed (μs)	1.8	1.5

External Clock—An external clock may be connected directly to the clock input, Pin 19. When operating in this mode, the convert start should be held high for a minimum of one clock period in order to reset the SAR and synchronize the conversion cycle. A positive going pulse width of 100 to 200 nanoseconds will provide a continuous string of conversions that start on the first rising edge of the external clock after the EOC output has gone low.

External Buffer Amplifier—In applications where the AD578 is to be driven from high impedance sources or directly from an analog multiplexer a fast slewing, wideband op amp like the AD711 should be used.

Low Cost Signal Conditioning 8-Bit ADC

AD670

FEATURES

- **Complete 8-Bit Signal Conditioning A/D Converter Including Instrumentation Amp and Reference**
- **Microprocessor Bus Interface**
- **10μs Conversion Speed**
- **Flexible Input Stage: Instrumentation Amp Front End Provides Differential Inputs and High Common-Mode Rejection**
- **No User Trims Required**
- **No Missing Codes Over Temperature**
- **Single +5V Supply Operation**
- **Convenient Input Ranges**
- **20-Pin DIP or Surface-Mount Package**
- **Low Cost Monolithic Construction**
- **MIL-STD-883B Compliant Versions Available**

GENERAL DESCRIPTION

The AD670 is a complete 8-bit signal conditioning analog-to-digital converter. It consists of an instrumentation amplifier front end along with a DAC, comparator, successive approximation register (SAR), precision voltage reference, and a three-state output buffer on a single monolithic chip. No external components or user trims are required to interface, with full accuracy, an analog system to an 8-bit data bus. The AD670 will operate on the +5V system supply. The input stage provides differential inputs with excellent common-mode rejection and allows direct interface to a variety of transducers.

The device is configured with input scaling resistors to permit two input ranges: 0 to 255mV (1mV/LSB) and 0 to 2.55V (10mV/LSB). The AD670 can be configured for both unipolar and bipolar inputs over these ranges. The differential inputs and common-mode rejection of this front end are useful in applications such as conversion of transducer signals superimposed on common-mode voltages.

The AD670 incorporates advanced circuit design and proven processing technology. The successive approximation function is implemented with I^2L (integrated injection logic). Thin-film SiCr resistors provide the stability required to prevent missing codes over the entire operating temperature range while laser wafer trimming of the resistor ladder permits calibration of the device to within ±1LSB. Thus, no user trims for gain or offset are required. Conversion time of the device is 10μs.

The AD670 is available in four package types and five grades. The J and K grades are specified over 0 to +70°C and come in 20-pin plastic DIP packages or 20-terminal PLCC packages. The A and B grades (−40°C to +85°C) and the S grade (−55°C to +125°C) come in 20-pin ceramic DIP packages.

The S grade is also available with optional processing to MIL-STD-883 in 20-pin ceramic DIP or 20-terminal LCC packages. The Analog Devices Military Products Databook should be consulted for detailed specifications.

PRODUCT HIGHLIGHTS

1. The AD670 is a complete 8-bit A/D including three-state outputs and microprocessor control for direct connection to 8-bit data buses. No external components are required to perform a conversion.
2. The flexible input stage features a differential instrumentation amp input with excellent common-mode rejection. This allows direct interface to a variety of transducers without preamplification.
3. No user trims are required for 8-bit accurate performance.
4. Operation from a single +5V supply allows the AD670 to run off of the microprocessor's supply.
5. Four convenient input ranges (two unipolar and two bipolar) are available through internal scaling resistors: 0 to 255mV (1mV/LSB) and 0 to 2.55V (10mV/LSB).
6. Software control of the output mode is provided. The user can easily select unipolar or bipolar inputs and binary or 2's complement output codes.

CIRCUIT OPERATION/FUNCTIONAL DESCRIPTION

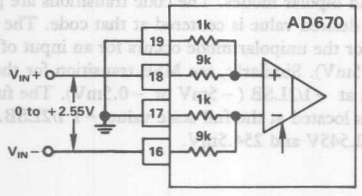
The AD670 is a functionally complete 8-bit signal conditioning A/D converter with microprocessor compatibility. The input section uses an instrumentation amplifier to accomplish the voltage to current conversion. This front end provides a high impedance, low bias current differential amplifier. The common-mode range allows the user to directly interface the device to a variety of transducers.

The A/D conversions are controlled by R/$\overline{W}$, $\overline{CS}$, and $\overline{CE}$. The R/$\overline{W}$ line directs the converter to read or start a conversion. A minimum write/start pulse of 300ns is required on either $\overline{CE}$ or $\overline{CS}$. The STATUS line goes high, indicating that a conversion is in process. The conversion thus begun, the internal 8-bit DAC is sequenced from MSB to LSB using a novel successive approximation technique. In conventional designs, the DAC is stepped through the bits by a clock. This can be thought of as a static design since the speed at which the DAC is sequenced is determined solely by the clock. No clock is used in the AD670. Instead, a "dynamic SAR" is created consisting of a string of inverters with taps along the delay line. Sections of the delay line between taps act as one shots. The pulses are used to set and reset the DAC's bits and strobe the comparator. When strobed, the comparator then determines whether the addition of each successively weighted bit current causes the DAC current sum to be greater or less than the input current. If the sum is less, the bit is turned off. After all bits are tested, the SAR holds an 8-bit code representing the input signal to within 1/2LSB accuracy. Ease of implementation and reduced dependence on process related variables make this an attractive approach to a successive approximation design.

The SAR provides an end-of-conversion signal to the control logic which then brings the STATUS line low. Data outputs remain in a high impedance state until R/$\overline{W}$ is brought high with $\overline{CE}$ and $\overline{CS}$ low and allows the converter to be read. Bringing $\overline{CE}$ or $\overline{CS}$ high during the valid data period ends the read cycle. The output buffers cannot be enabled during a conversion. Any convert start commands will be ignored until the conversion cycle is completed; once a conversion cycle has been started it cannot be stopped or restarted.

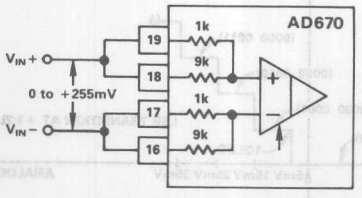
The AD670 provides the user with a great deal of flexibility by offering two input spans and formats and a choice of output codes. Input format and input range can each be selected. The BPO/$\overline{UPO}$ pin controls a switch which injects a bipolar offset current of a value equal to the MSB less 1/2LSB into the summing node of the comparator to offset the DAC output. Two precision 10 to 1 attenuators are included on board to provide input range selection of 0 to 2.55V or 0 to 255mV. Additional ranges of

– 1.28 to 1.27V and – 128 to 127mV are possible if the BPO/$\overline{\text{UPO}}$ switch is high when the conversion is started. Finally, output coding can be chosen using the FORMAT pin when the conversion is started. In the bipolar mode and with a logic 1 on FORMAT, the output is in two's complement; with a logic 0, the output is offset binary.



CONNECTING THE AD670

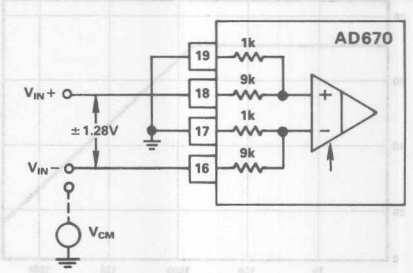
The AD670 has been designed for ease of use. All active components required to perform a complete A/D conversion are on board and are connected internally. In addition, all calibration trims are performed at the factory, assuring specified accuracy without user trims. There are, however, a number of options and connections that should be considered to obtain maximum flexibility from the part.



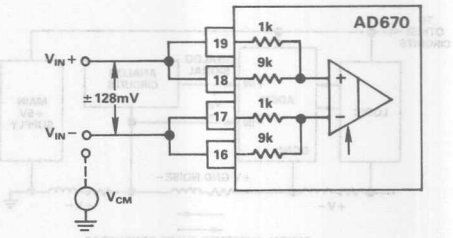
INPUT CONNECTIONS

Standard connections are shown in the figures that follow. An input range of 0 to 2.55V may be configured as shown in Figure 2a. This will provide a one LSB change for each 10mV of input change. The input range of 0 to 255mV is configured as shown in Figure 2b. In this case, each LSB represents 1mV of input change. When unipolar input signals are used, Pin 11, BPO/$\overline{\text{UPO}}$, should be grounded. Pin 11 selects the input format for either unipolar or bipolar signals. Figures 3a and 3b show the input connections for bipolar signals. Pin 11 should be tied to $+V_{CC}$ for bipolar inputs.

Although the instrumentation amplifier has a differential input, there must be a return path to ground for the bias currents. If it is not provided, these currents will charge stray capacitances and cause internal circuit nodes to drift uncontrollably causing the digital output to change. Such a return path is provided in Figures 2a and 3a (larger input ranges) since the 1k resistor leg



2a. 0 to 2.55V (10mV/LSB)



2b. 0 to 255mV (1mV/LSB)

NOTE: PIN 11, BPO/$\overline{\text{UPO}}$ SHOULD BE LOW WHEN CONVERSION IS STARTED.

Figure 2. Unipolar Input Connections

3a. ± 1.28V Range

3b. ± 128mV Range

NOTE: PIN 11, BPO/$\overline{\text{UPO}}$ SHOULD BE HIGH WHEN CONVERSION IS STARTED.

Figure 3. Bipolar Input Connections

is tied to ground. This is not the case for Figures 2b and 3b (the lower input ranges). When connecting the AD670 inputs to floating sources, such as transformers and ac-coupled sources, there must still be a dc path from each input to common. This can be accomplished by connecting a 10kΩ resistor from each input to ground.

Bipolar Operation

Through special design of the instrumentation amplifier, the AD670 accommodates input signal excursions below ground, even though it operates from a single 5V supply. To the user, this means that true bipolar input signals can be used without the need for any additional external components. Bipolar signals can be applied differentially across both inputs, or one of the inputs can be grounded and a bipolar signal applied to the other.

Common-Mode Performance

The AD670 is designed to reject dc and ac common-mode voltages. In some applications it is useful to apply a differential input signal V_{IN} in the presence of a dc common-mode voltage V_{CM}. The user must observe the absolute input signal limits listed in the specifications, which represent the maximum voltage V_{IN} + V_{CM} that can be applied to either input without affecting proper operation. Exceeding these limits (within the range of absolute maximum ratings), however, will not cause permanent damage.

The excellent common-mode rejection of the AD670 is due to the instrumentation amplifier front end, which maintains the differential signal until it reaches the output of the comparator. In contrast to a standard operational amplifier, the instrumentation amplifier front end provides significantly improved CMRR over a wide frequency range (Figure 4a).

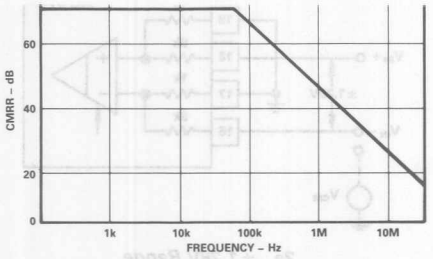


Figure 4a. CMRR over Frequency

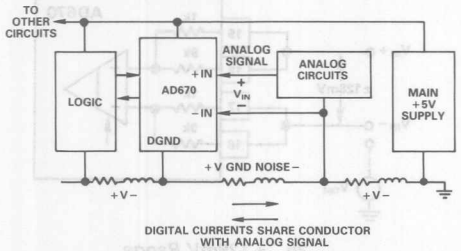

Figure 4b. AD670 Input Rejects Common-Mode Ground Noise

Good common-mode performance is useful in a number of situations. In bridge-type transducer applications, such performance facilitates the recovery of differential analog signals in the presence of a dc common-mode or a noisy electrical environment. High-frequency CMRR also becomes important when the analog signal is referred to a noisy, remote digital ground. In each case, the CMRR specification of the AD670 allows the integrity of the input signal to be preserved.

The AD670's common-mode voltage tolerance allows great flexibility in circuit layout. Most other A/D converters require the establishment of one point as the analog reference point. This is necessary in order to minimize the effects of parasitic voltages. The AD670, however, eliminates the need to make the analog ground reference point and A/D analog ground one and the same. Instead, a system such as that shown in Figure 4b is possible as a result of the AD670's common-mode performance. The resistors and inductors in the ground return represent unavoidable system parasitic impedances.

Input/Output Options

Data output coding (2's complement vs. straight binary) is selected using Pin 12, the FORMAT pin. The selection of input format (bipolar vs. unipolar) is controlled using Pin 11, BPO/$\overline{\text{UPO}}$. Prior to a write/convert, the state of FORMAT and BPO/$\overline{\text{UPO}}$ should be available to the converter. These lines may be tied to the data bus and may be changed with each conversion if desired. The configurations are shown in Table I. Output coding for representative signals in each of these configurations is shown in Figure 5.

An output signal, STATUS, indicates the status of the conversion. STATUS goes high at the beginning of the conversion and returns low when the conversion cycle has been completed.

Calibration

Because of its precise factory calibration, the AD670 is intended to be operated without user trims for gain and offset; therefore, no provisions have been made for such user trims. Figures 6a, 6b, and 6c show the transfer curves at zero and full scale for the unipolar and bipolar modes. The code transitions are positioned so that the desired value is centered at that code. The first LSB transition for the unipolar mode occurs for an input of +1/2LSB (5mV or 0.5mV). Similarly, the MSB transition for the bipolar mode is set at –1/2LSB (–5mV or –0.5mV). The full scale transition is located at the full scale value –1 1/2LSB. These values are 2.545V and 254.5mV.

CONTROL AND TIMING OF THE AD670

Control Logic

The AD670 contains on-chip logic to provide conversion and data read operations from signals commonly available in microprocessor systems. Figure 7 shows the internal logic circuitry of the AD670. The control signals, $\overline{CE}$, $\overline{CS}$, and R/$\overline{W}$ control the operation of the converter. The read or write function is determined by R/$\overline{W}$ when both $\overline{CS}$ and $\overline{CE}$ are low as shown in Table II. If all three control inputs are held low longer than the conversion time, the device will continuously convert until one input, $\overline{CE}$, $\overline{CS}$, or R/$\overline{W}$ is brought high. The relative timing of these signals is discussed later in this section.

Timing

The AD670 is easily interfaced to a variety of microprocessors and other digital systems. The following discussion of the timing requirements of the AD670 control signals will provide the designer with useful insight into the operation of the device.

Write/Convert Start Cycle

Figure 8 shows a complete timing diagram for the write/convert start cycle. $\overline{CS}$ (chip select) and $\overline{CE}$ (chip enable) are active low and are interchangeable signals. Both $\overline{CS}$ and $\overline{CE}$ must be low for the converter to read or start a conversion. The minimum pulse width, t_W, on either $\overline{CS}$ or $\overline{CE}$ is 300ns to start a conversion.

Table III. AD670 TIMING SPECIFICATIONS

Boldface indicates parameters tested 100% unless otherwise noted. See Specifications page for explanation.

		@ +25°C			
Symbol	Parameter	Min	Typ	Max	Units
WRITE/CONVERT START MODE					
t_W	Write/Start Pulse Width	300			ns
t_{DS}	Input Data Setup Time	200			ns
t_{DH}	Input Data Hold	10			ns
t_{RWC}	Read/Write Setup Before Control	0			ns
t_{DC}	Delay to Convert Start			700	ns
t_C	**Conversion Time**			**10**	µs
READ MODE					
t_R	Read Time	250			ns
t_{SD}	Delay from Status Low to Data Read			250	ns
t_{TD}	**Bus Access Time**		200	**250**	ns
t_{DH}	Data Hold Time	25			ns
t_{DT}	**Output Float Delay**			**150**	ns
t_{RT}	R/$\overline{W}$ before $\overline{CE}$ or $\overline{CS}$ low	0			ns

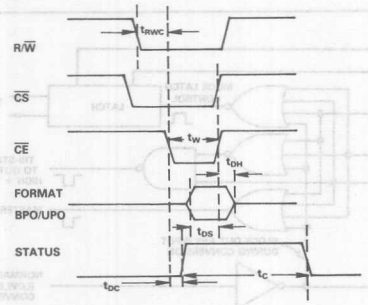

Figure 8. Write/Convert Start Timing

The R/$\overline{W}$ line is used to direct the converter to start a conversion (R/$\overline{W}$ low) or read data (R/$\overline{W}$ high). The relative sequencing of the three control signals (R/$\overline{W}$, $\overline{CE}$, $\overline{CS}$) is unimportant. However, when all three signals remain low for at least 300ns (t_W), STATUS will go high to signal that a conversion is taking place.

Once a conversion is started and the STATUS line goes high, convert start commands will be ignored until the conversion cycle is complete. The output data buffer cannot be enabled during a conversion.

Read Cycle

Figure 9 shows the timing for the data read operation. The data outputs are in a high impedance state until a read cycle is initiated. To begin the read cycle, R/$\overline{W}$ is brought high. During a read cycle, the minimum pulse length for $\overline{CE}$ and $\overline{CS}$ is a function of the length of time required for the output data to be valid. The data becomes valid and is available to the data bus in a maximum of 250ns. This delay between the high impedance state and valid data is the maximum bus access time or t_{TD}. Bringing $\overline{CE}$ or $\overline{CS}$ high during valid data ends the read cycle. The outputs remain valid for a minimum of 25ns (t_{DH}) and return to the high impedance state after a delay, t_{DT}, of 150ns maximum.

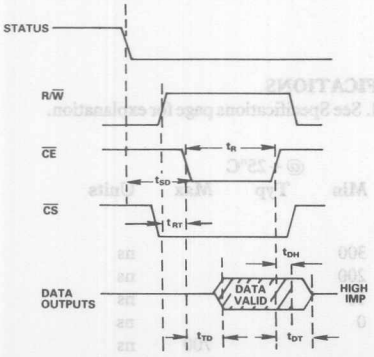

Figure 9. Read Cycle Timing

STAND-ALONE OPERATION

The AD670 can be used in a "stand-alone" mode, which is useful in systems with dedicated input ports available. Two typical conditions are described and illustrated by the timing diagrams which follow.

Single Conversion, Single Read

When the AD670 is used in a stand-alone mode, $\overline{CS}$ and $\overline{CE}$ should be tied together. Conversion will be initiated by bringing R/$\overline{W}$ low. Within 700ns, a conversion will begin. The R/$\overline{W}$ pulse should be brought high again once the conversion has started so that the data will be valid upon completion of the conversion. Data will remain valid until $\overline{CE}$ and $\overline{CS}$ are brought high to indicate the end of the read cycle or R/$\overline{W}$goes low. The timing diagram is shown in Figure 10.

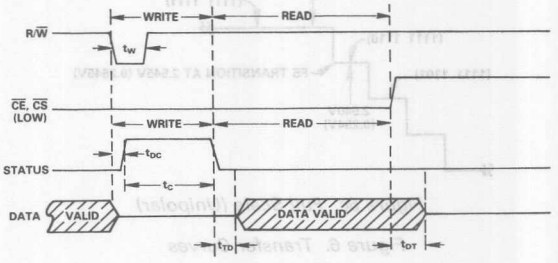

Figure 10. Stand-Alone Mode Single Conversion/ Single Read

Continuous Conversion, Single Read

A variety of applications may call for the A/D to be read after several conversions. In process control systems, this is often the case since a reading from a sensor may only need to be updated every few conversions. Figure 11 shows the timing relationships.

Once again, $\overline{CE}$ and $\overline{CS}$ should be tied together. Conversion will begin when the R/$\overline{W}$ signal is brought low. The device will convert repeatedly as indicated by the status line. A final conversion will take place once the R/$\overline{W}$ line has been brought high. The rising edge of R/$\overline{W}$ must occur while STATUS is high. R/$\overline{W}$ should not return high while STATUS is low since the circuit is in a reset state prior to the next conversion. Since the rising edge of R/$\overline{W}$ must occur while STATUS is high, R/$\overline{W}$'s length must be a minimum of 10.25µs (t_C + t_{TD}). Data becomes valid upon completion of the conversion and will remain so until the $\overline{CE}$ and $\overline{CS}$ lines are brought high indicating the end of the read cycle or R/$\overline{W}$ goes low initiating a new series of conversions.

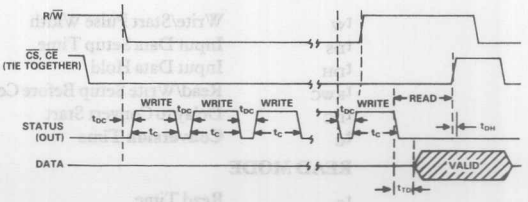

Figure 11. Stand-Alone Mode Continuous Conversion/ Single Read

APPLYING THE AD670

The AD670 has been designed for ease of use, system compatibility, and minimization of external components. Transducer interfaces generally require signal conditioning and preamplification before the signal can be converted. The AD670 will reduce and even eliminate this excess circuitry in many cases. To illustrate the flexibility and superior solution that the AD670 can bring to a transducer interface problem, the following discussions are offered.

Temperature Measurements

Temperature transducers are one of the most common sources of analog signals in data acquisition systems. These sensors require circuitry for excitation and preamplification/buffering. The instrumentation amplifier input of the AD670 eliminates the need for this signal conditioning. The output signals from temperature transducers are generally sufficiently slow that a sample/hold amplifier is not required. Figure 12 shows the AD590 IC temperature transducer interfaced to the AD670. The AD580 voltage reference is used to offset the input for 0°C calibration. The current output of the AD590 is converted into a voltage by R1. The high impedance unbuffered voltage is applied directly to the AD670 configured in the −128mV to 127mV bipolar range. The digital output will have a resolution of 1°C.

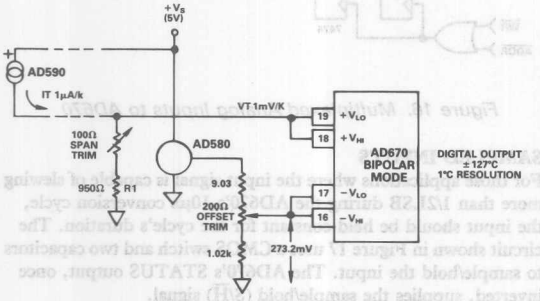

Figure 12. AD670 Temperature Transducer Interface

Platinum RTDs are also a popular, temperature transducer. Typical RTDs have a resistance of 100Ω at 0°C and change resistance 0.4Ω per °C. If a constant excitation current is caused to flow in the RTD, the change in voltage drop will be a measure of the change in temperature. Figure 13 shows such a method and the required connections to the AD670. The AD580 2.5V reference provides the accurate voltage for the excitation current and range offsetting for the RTD. The op-amp is configured to force a constant 2.5mA current through the RTD. The differential inputs of the AD670 measure the difference between a fixed offset voltage and the temperature dependent output of the op-amp which varies with the resistance of the RTD. The RTD change of approximately 0.4Ω/°C results in a 1mV/°C voltage change. With the AD670 in the 1mV/LSB range, temperatures from 0 to 255°C can be measured.

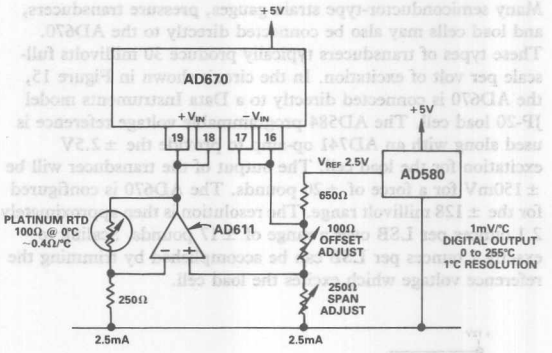

Figure 13. Low Cost RTD Interface

Differential temperature measurements can be made using an AD590 connected to each of the inputs as shown in Figure 14. This configuration will allow the user to measure the relative temperature difference between two points with a 1°C resolution. Although the internal 1k and 9k resistors on the inputs have ±20% tolerance, trimming the AD590 is unnecessary as most differential temperature applications are concerned with the relative differences between the two. However, the user may see up to a 20% scale factor error in the differential temperature to digital output transfer curve.

This scale factor error can be eliminated through a software correction. Offset corrections can be made by adjusting for any difference that results when both sensors are held at the same temperature. A span adjustment can then be made by immersing one AD590 in an ice bath and one in boiling water and eliminating any deviation from 100°C. For a low cost version of this setup, the plastic AD592 can be substituted for the AD590.

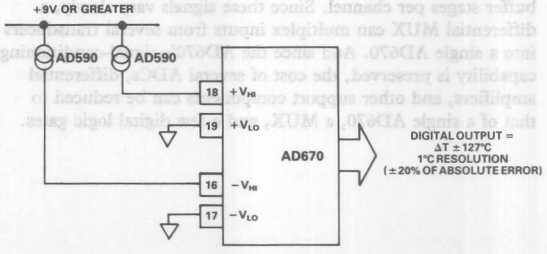

Figure 14. Differential Temperature Measurement Using the AD590

STRAIN GAUGE MEASUREMENTS

Many semiconductor-type strain gauges, pressure transducers, and load cells may also be connected directly to the AD670. These types of transducers typically produce 30 millivolts full-scale per volt of excitation. In the circuit shown in Figure 15, the AD670 is connected directly to a Data Instruments model JP-20 load cell. The AD584 programmable voltage reference is used along with an AD741 op-amp to provide the ±2.5V excitation for the load cell. The output of the transducer will be ±150mV for a force of ±20 pounds. The AD670 is configured for the ±128 millivolt range. The resolution is then approximately 2.1 ounces per LSB over a range of ±17 pounds. Scaling to exactly 2 ounces per LSB can be accomplished by trimming the reference voltage which excites the load cell.

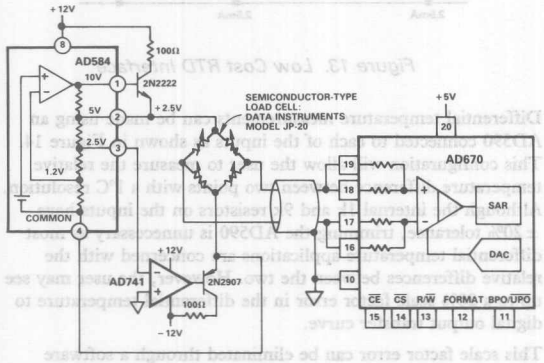

Figure 15. AD670 Load Cell Interface

MULTIPLEXED INPUTS

Most data acquisition systems require the measurement of several analog signals. Multiple A/D converters are often used to digitize these inputs, requiring additional preamplification and buffer stages per channel. Since these signals vary slowly, a differential MUX can multiplex inputs from several transducers into a single AD670. And since the AD670's signal-conditioning capability is preserved, the cost of several ADCs, differential amplifiers, and other support components can be reduced to that of a single AD670, a MUX, and a few digital logic gates.

An AD7502 dual 4-channel MUX appears in Figure 16 multiplexing four differential signals to the AD670. The AD7502's decoded address is gated with the microprocessor's write signal to provice a latching strobe at the flip-flops. A write cycle to the AD7502's address then latches the two LSBs of the data word thereby selecting the input channel for subsequent conversions.

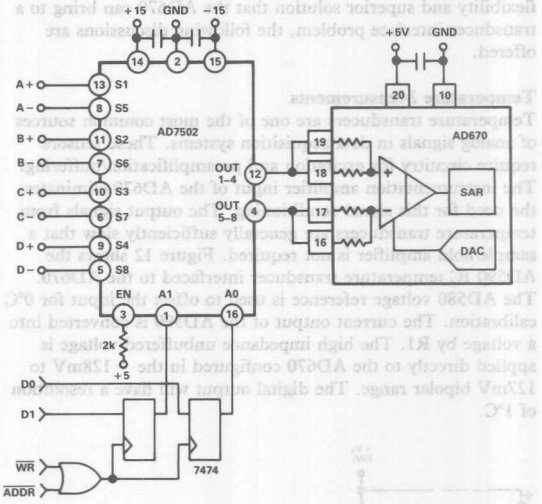

Figure 16. Multiplexed Analog Inputs to AD670

SAMPLED INPUTS

For those applications where the input signal is capable of slewing more than 1/2LSB during the AD670's 10μs conversion cycle, the input should be held constant for the cycle's duration. The circuit shown in Figure 17 uses a CMOS switch and two capacitors to sample/hold the input. The AD670's STATUS output, once inverted, supplies the sample/hold ($S/\overline{H}$) signal.

A convert command applied on the $\overline{CE}$, $\overline{CS}$ OR $R/\overline{W}$ lines will initiate the conversion. The AD670's STATUS output, once inverted, supplies the sample/hold signal to the CD4066. The CD4066 CMOS switch shown in Figure 17 was chosen for its fast transition times, low on-resistance and low cost. The control input's propagation delay for switch-closed to switch-open should remain less than 150ns to ensure that the sample-to-hold transition occurs before the first bit decision in the AD670.

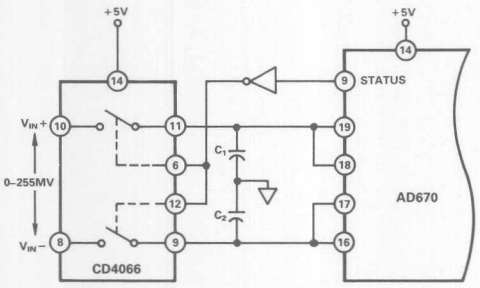

Figure 17. Low Cost Sample-and-Hold Circuit for AD670

Since settling to 1/2LSB at 8-bits of resolution requires 6.2 RC time constants, the 500pF hold capacitors and CD4066's 300Ω on-resistance yield an acquisition time of under 1μs, assuming a low impedance source.

This sample/hold approach makes use of the differential capabilities of the AD670. Because 500pF hold capacitors are used on both V_{IN}+ and V_{IN}− inputs, the droop rate depends only on the offset current of the AD670, typically 20nA. With the matched 500pF capacitors, the droop rate is 40μV/μs. The input will then droop only 0.4mV (0.4LSB) during the AD670's 10μs conversion time. The differential approach also minimizes pedestal error since only the difference in charge injection between the two switches results in errors at the A/D.

The fast conversion time and differential and common-mode capabilities of the AD670 permit this simple sample-hold design to perform well with low sample-to-hold offset, droop rate of about 40μV/μs and acquisition time under 1μs. The effective aperture time of the AD670 is reduced by about 2 orders of magnitude with this circuit, allowing frequencies to be converted up to several kilohertz.

While no input anti-aliasing filter is shown, filtering will be necessary to prevent output errors if higher frequencies are present in the input signal. Many practical variations are possible with this circuit, including input MUX control, for digitizing a number of AC channels.

IBM PC INTERFACE

The AD670 appears in Figure 18 interfaced to the IBM PC. Since the device resides in I/O space, its address is decoded from only the lower ten address lines and must be gated with AEN (active low) to mask out internal (DMA) cycles which use the same I/O address space. This active low signal is applied to $\overline{CS}$. AO, meanwhile, is reserved for the R/$\overline{W}$ input. This places

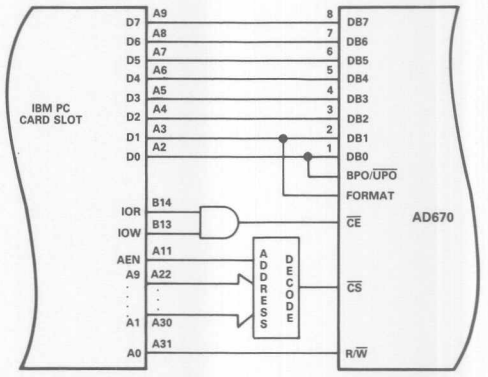

Figure 18. IBM PC Interface to AD670

the AD670 in two adjacent addresses; one for starting the conversion and the other for reading the result. The $\overline{IOR}$ and $\overline{IOW}$ signals are then gated and applied to $\overline{CE}$, while the lower two data lines are applied to FORMAT and BPO/$\overline{UPO}$ inputs to provide software programmable input formats and output coding.

In BASIC, a simple OUT ADDR, WORD command initiates a conversion. While the upper six bits of the data WORD are meaningless, the lower two bits define the analog input format and digital output coding according to Table IV. The data is available ten microseconds later (which is negligible in BASIC) and can be read using INP (ADDR + 1). The 3-line subroutine in Figure 19, used in conjunction with the interface of Figure 18, converts an analog input within a bipolar range to an offset binary coded digital word.

NOTE: Due to the large number of options that may be installed in the PC, the I/O bus loading should be limited to one Schottky TTL load. Therefore, a buffer/driver should be used when interfacing more than two AD670's to the I/O bus.

DATA	INPUT FORMAT	OUTPUT CODING
0	Unipolar	Straight Binary
1	Bipolar	Offset Binary
2	Unipolar	2's Complement
3	Bipolar	2's Complement

12-Bit Resolution
24-Pin "Skinny DIP" Package
Conversion Time: 500 ns max – AD671J/K/S-500
750 ns max – AD671J/K/S-750
Low Power: 475 mW
Unipolar (0 to +5 V, 0 to +10 V) and Bipolar Input Ranges (±5 V)
Twos Complement or Offset Binary Output Data
Out of Range Indicator
MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD671 is a high speed monolithic 12-bit A/D converter offering conversion rates of up to 2 MHz (500 ns conversion time). The combination of a merged high speed bipolar/CMOS process and a novel architecture results in a combination of speed and power consumption far superior to previously available hybrid implementations. Additionally, the greater reliability of monolithic construction offers improved system reliability and lower costs than hybrid designs.

The AD671 uses a subranging flash conversion technique, with digital error correction for possible errors introduced in the first part of the conversion cycle. An on-chip timing generator provides strobe pulses for each of the four internal flash cycles and assures adequate settling time for the interflash residue amplifier. A single ENCODE pulse is used to control the converter.

The performance of the AD671 is made possible by using high speed, low noise bipolar circuitry in the linear sections and low power CMOS for the logic sections. Analog Devices' ABCMOS-1 process provides both high speed bipolar and 2-micron CMOS devices on a single chip. Laser trimmed thin-film resistors are used to provide accuracy and temperature stability.

The AD671 is available in two conversion speeds and performance grades. The AD671J and K grades are specified for operation over the 0 to +70°C temperature range. The AD671S grades are specified for operation over the −55°C to +125°C temperature range. All grades are available in a 0.300 inch wide 24-pin ceramic DIP. The J and K grades are also available in a 24-pin plastic DIP.

PRODUCT HIGHLIGHTS

1. The AD671 offers a single chip 2 MHz analog-to-digital conversion function in a space saving 24-pin DIP.
2. Input signal ranges are 0 to +5 V and 0 to +10 V unipolar, and −5 V to +5 V bipolar, selected by pin strapping. Input resistance is 1.5 kΩ. Power supplies are +5 V and −5 V, and typical power consumption is less than 500 mW.
3. The external +5 V reference can be chosen to suit the dc accuracy and temperature drift requirements of the application.
4. Output data is available in unipolar, bipolar offset or bipolar twos complement binary format.
5. An OUT OF RANGE output bit indicates when the input signal is beyond the AD671's input range.
6. The AD671 is available in versions compliant with the MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD671/883B data sheet for detailed specifications.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum ratings for extended periods may effect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

AD671 PIN DESCRIPTION

Symbol	Pin	Type	Name and Function
ACOM	22	P	Analog Ground.
AIN	20	AI	Analog Input Signal.
BIT1 (MSB)	12	DO	Most Significant Bit.
BIT2–BIT11	11–2	DO	Data Bits 2–11.
BIT12 (LSB)	1	DO	Least Significant Bit.
BPO/UPO	21	AI	Bipolar or Unipolar Configuration Pin. Connect to AIN for 0 to +5 V Span, to ACOM for 0 to +10 V Span and to REF IN for −5 V to +5 V Span.
DAV	15	DO	Data Available Output. The Rising Edge of DAV Indicates an End of Conversion and Can Be Used to Latch Current Data into an External Register. The Falling Edge of DAV Can Be Used to Latch Previous Data into an External Register.
DCOM	18	P	Digital Ground.
ENCODE	16	DI	The AD671 Starts a Conversion on the Rising Edge of the ENCODE Pulse.
$\overline{\text{MSB}}$	13	DO	Inverted Most Significant Bit. Provides Twos Complement Output Data Format.
OTR	14	DO	Out of Range Is Active HIGH when the analog input is beyond the input range of the converter.
REF IN	19	AI	+5 V Reference Input.
V_{CC}	23	P	+5 V Analog Power.
V_{EE}	24	P	−5 V Analog Power.
V_{LOGIC}	17	P	+5 V Digital Power.

TYPE:
AI = Analog Input
DI = Digital Input
DO = Digital Output
P = Power

CONNECTION DIAGRAM
PINOUT

Integral nonlinearity refers to the deviation of each individual code from a line drawn from "zero" through "full scale." The point used as "zero" occurs 1/2 LSB (1.22 mV for a 10 V span) before the first code transition (all zeros to only the LSB on). "Full scale" is defined as a level 1 1/2 LSB beyond the last code transition (to all ones). The deviation is measured from the low side transition of each particular code to the true straight line.

DIFFERENTIAL NONLINEARITY (DNL, NO MISSING CODES)
An ideal ADC exhibits code transitions that are exactly 1 LSB apart. DNL is the deviation from this ideal value. Thus every code must have a finite width. Guaranteed no missing codes to 10-bit resolution indicates that all 1024 codes represented by Bits 1–10 must be present over all operating ranges. Guaranteed no missing codes to 11- or 12-bit resolution indicates that all 2048 and 4096 codes, respectively, must be present over all operating ranges.

UNIPOLAR OFFSET
The first transition should occur at a level 1/2 LSB above analog common. Unipolar offset is defined as the deviation of the actual from that point. This offset can be adjusted as discussed later. The unipolar offset temperature coefficient specifies the maximum change of the transition point over temperature, with or without external adjustments.

BIPOLAR ZERO
In the bipolar mode the major carry transition (0111 1111 1111 to 1000 0000 0000) should occur for an analog value 1/2 LSB below analog common. The bipolar offset error and temperature coefficient specify the initial deviation and maximum change in the error over temperature.

should occur for an analog value 1 1/2 LSB below the nominal full scale (9.9963 volts for 10.000 volts full scale). The gain error is the deviation of the actual level at the last transition from the ideal level. The gain error can be adjusted to zero as shown in Figures 7, 8 and 9.

TEMPERATURE COEFFICIENTS
The temperature coefficients for unipolar offset, bipolar zero and gain error specify the maximum change from the initial (+25°C) value to the value at T_{MIN} or T_{MAX}.

POWER SUPPLY REJECTION
The only effect of power supply error on the performance of the device will be a small change in gain. The specifications show the maximum full-scale change from the initial value with the supplies at the various limits.

SIGNAL-TO-NOISE AND DISTORTION (S/N+D) RATIO
S/N+D is the ratio of the rms value of the measured input signal to the rms sum of all other spectral components, including harmonics but excluding dc. The value for S/N+D is expressed in decibels.

EFFECTIVE NUMBER OF BITS (ENOB)
ENOB is calculated from the expression SNR = 6.02N + 1.8 dB, where N is equal to the effective number of bits.

TOTAL HARMONIC DISTORTION (THD)
THD is the ratio of the rms sum of the first six harmonic components to the rms value of the measured input signal and is expressed as a percentage or in decibels.

PEAK SPURIOUS OR PEAK HARMONIC COMPONENT
The peak spurious or peak harmonic component is the largest spectral component excluding the input signal and dc. This value is expressed in decibels relative to the rms value of a full-scale input signal.

Theory of Operation

The AD671 uses a successive subranging architecture. The analog to digital conversion takes place in four independent steps or flashes. The analog input signal is subranged to an intermediate residue voltage for the final 12-bit result by utilizing multiple flashes with subtraction DACs (see the AD671 functional block diagram).

The AD671 can be configured to operate with unipolar (0 to +5 V, 0 to +10 V) or bipolar (±5 V) inputs by connecting AIN (Pin 20), REFIN (Pin 19) and BPO/UPO (Pin 21) as shown in Figure 2.

The AD671 conversion cycle begins by simply providing an active HIGH pulse on the ENCODE pin (Pin 16). The rising edge of the ENCODE pulse starts the conversion. The falling edge of the ENCODE pulse is specified to operate within a window of time: less than 30 ns after the rising edge of ENCODE (AD671-500) and less than 50 ns after the falling edge of ENCODE (AD671-750) or after the falling edge of DAV. The time window prevents digitally coupled noise from being introduced during the final stages of conversion. An internal timing generator circuit accurately controls all internal timing.

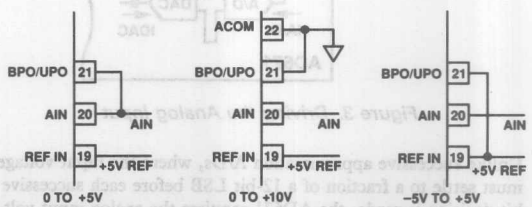

Figure 2. Input Range Connections

Upon receipt of an ENCODE command, the first 3-bit flash converts the analog input voltage. The 3-bit result is passed to a correction logic register and a segmented current output DAC. The DAC output is connected through a resistor (within the Range/Span Select Block) to AIN. A residue voltage is created by subtracting the DAC output from AIN, which is less than one eighth of the full-scale analog input. The second flash has an input range that is configured with one bit of overlap with the previous DAC. The overlap allows for errors during the flash conversion. The first residue voltage is connected to the second 3-bit flash and to the noninverting input of a high speed, differential, gain-of-four amplifier. The second flash result is passed to the correction logic register and to the second segmented current output DAC. The output of the second DAC is connected to the inverting input of the differential amplifier. The differential amplifier output is connected to a two step backend 8-bit flash. This 8-bit flash consists of coarse and fine flash converters. The result of the coarse 4-bit flash converter, also configured to overlap one bit of DAC 2, is connected to the correction logic register and selects one of 16 resistors from which the fine 4-bit flash will establish its span voltage. The fine 4-bit flash is connected directly to the output latches.

The AD671 will flag an out-of-range condition when the input voltage exceeds the analog input range. OTR (Pin 14) is active HIGH when an out of range high or low condition exists. Bits 1–12 are HIGH when the analog input voltage is greater than the selected input range and LOW when the analog input is less than the selected input range.

APPLYING THE AD671

DRIVING THE AD671 ANALOG INPUT

The AD671 uses a very high speed current output DAC to subtract a known voltage from the analog input. This results in very fast steps of current at the analog input. It is important to recognize that the signal source driving the analog input of the AD671 must be capable of maintaining the input voltage under dynamically-changing load conditions. When the AD671 starts its conversion cycle, the subtraction DAC will sink up to 5 mA (see Figure 3) from the source driving the analog input. The source must respond to this current step by settling the input voltage back to a fraction of an LSB before the AD671 makes its final 12-bit decision.

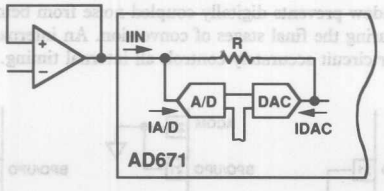

Figure 3. Driving the Analog Input

Unlike successive approximation A/Ds, where the input voltage must settle to a fraction of a 12-bit LSB before each successive bit decision is made, the AD671 requires the analog input voltage settle to within 12-bits before the third flash conversion, approximately 200 ns. This "free" 200 ns is useful in applications requiring a sample-and-hold amplifier (SHA), overlapping the SHA's hold mode settling time within the 200 ns window will increase total system throughput. See the "Discrete Sample-and-Hold" section for a high speed SHA application.

INPUT BUFFER AMPLIFIER

The closed-loop output impedance of an op amp is equal to the open loop output impedance (usually a few hundred ohms) divided by the loop gain at the frequency of interest. It is often assumed that loop gain of a follower-connected op amp is sufficiently high to reduce the closed-loop output impedance to a negligibly small value, particularly if the input signal is low frequency. At higher frequencies the open-loop gain is lower, increasing the output impedance which decreases the instantaneous analog input voltage and produces an error.

The recommended wideband, fast settling input amplifiers for use with the AD671 are the AD841, AD843, AD845 or the AD847. The AD841 is unity gain stable and recommended as a follower connected op amp. The AD843 and AD845 FET inputs make them ideal for high speed sample-and-hold amplifiers and the AD847 can be used as a low power, high speed buffer. Figure 4 shows the AD841 driving the AD671. As shown in the figure the analog input voltage should be produced with respect to the ACOM pin.

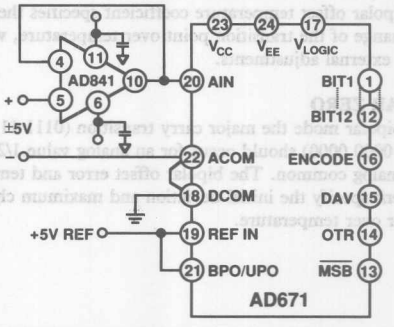

Figure 4. Input Buffer Amplifier

REFERENCE INPUT

The AD671 uses a standard +5 volt reference. The initial accuracy and temperature stability of the reference can be selected to meet specific system requirements. Like the analog input, fast switching input-dependent currents are modulated at the reference input pin (REF IN–Pin 19). However, unlike the analog input the reference input is held at a constant +5 volts with the use of capacitor. The recommended reference is the AD586, a +5 V precision reference with an output buffer amplifier. Figure 5 shows the AD671 configured in the ±5 V input range. The 6.8 μF capacitor maintains a constant +5 volts under the dynamically changing load conditions. An optional 1 μF noise reduction capacitor can be connected to the AD586, further reducing broadband output noise. To minimize ground voltage drops the AD586's ground pin should be tied as close as possible to the AD671's ACOM pin. See Figures 20, 21 and 22 for PCB layout recommendations.

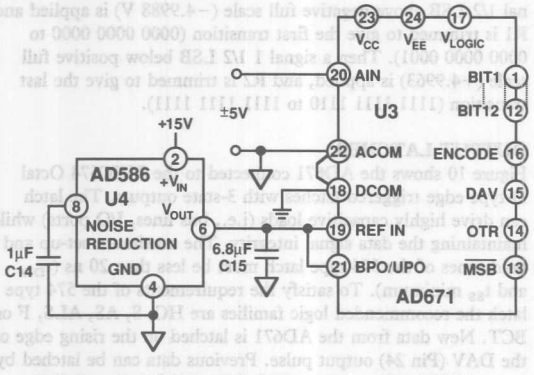

Figure 5. AD586 as Reference Input for AD671

GROUNDING AND DECOUPLING RULES

Proper grounding and decoupling should be a primary design objective in any high speed, high resolution system. The AD671 separates analog and digital grounds to optimize the management of analog and digital ground currents in a system. The AD671 is designed to minimize the current flowing from ACOM (Pin 22) by directing the majority of the current from V_{CC} (+5 V–Pin 23) to V_{EE} (−5 V–Pin 24). Minimizing analog ground currents hence reduces the potential for large ground voltage drops. This can be especially true in systems that do not utilize ground planes or wide ground runs. ACOM is also configured to be code independent, therefore reducing input dependent analog ground voltage drops and errors. The input current supplied by the external reference (REFIN–Pin 19) and the majority of the full-scale input signal (AIN–Pin 20) are also directed to V_{EE}. Also critical in any high speed digital design are the use of proper digital grounding techniques to avoid potential CMOS "ground bounce." Figure 6 is provided to assist in the proper layout, grounding and decoupling techniques.

Table I is a list of grounding and decoupling guidelines that should be reviewed before laying out a printed circuit board.

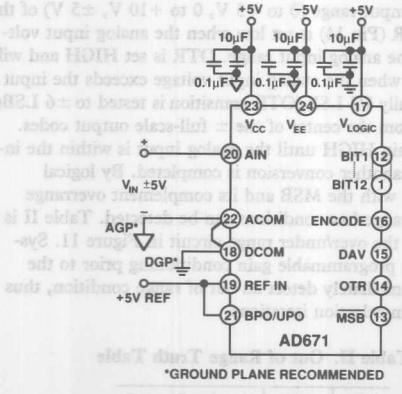

Figure 6. AD671 Grounding and Decoupling

Table I. Grounding and Decoupling Guidelines

Power Supply Decoupling	Comment
Capacitor Values	0.1 µF (Ceramic) and 10 µF (Tantalum). (Surface Mount Chip Capacitors Recommended to Reduce Lead Inductance)
Capacitor Locations	Directly at Positive and Negative Supply Pins to Respective Ground Plane.
Grounding	
Analog Ground	Ground Plane or Wide Ground Return Connected to the Analog Power Supply.
Digital Ground	Ground Plane or Wide Ground Return Connected to the Digital Power Supply.
Analog and Digital Ground	Connected Together Once at the AD671

UNIPOLAR (0 TO +10 V) CALIBRATION

The AD671 is factory trimmed to minimize offset, gain and linearity errors. In some applications the offset and gain errors of the AD671 need to be externally adjusted to zero. This is accomplished by trimming the voltage at BPO/UPO (Pin 21) and REFIN (Pin 19). In those applications the AD588, a high precision pin programmable voltage reference, is an ideal choice. The AD588 includes a reference cell and three additional amplifiers which can be configured to provide offset and gain trims for the AD671. The circuit in Figure 7 is recommended for calibrating offset and gain errors of the AD671 when configured in the 0 to +10 V input range.

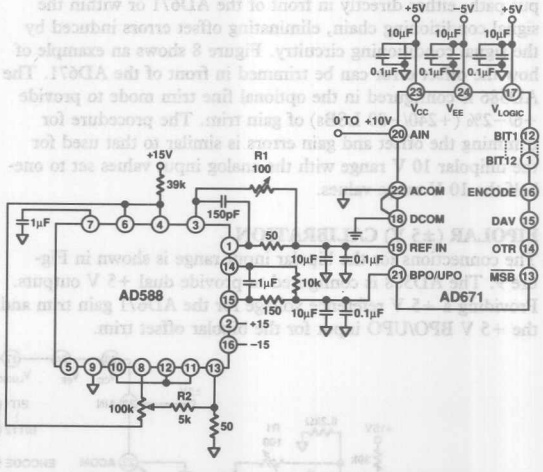

Figure 7. Unipolar (0 to +10 V) Calibration

The AD671 is intended to have a nominal 1/2 LSB offset so that the exact analog input for a given code will be in the middle of that code (halfway between the transitions to the codes above it and below it). Thus, the first transition (from 0000 0000 0000 to 0000 0000 0001) will occur for an input level of +1/2 LSB (1.22 mV for 10 V range). If the offset trim resistor R2 is used, it should be trimmed as above, although a different offset can be set for a particular system requirement. This circuit will give approximately ±50 mV of offset trim range.

The gain trim is done by applying a signal 1 1/2 LSBs below the nominal full scale (9.9963 for a 10 V range). Trim R1 to give the last transition (1111 1111 1110 to 1111 1111 1111).

UNIPOLAR (0 TO +5 V) CALIBRATION

The connections for the 0 to +5 V input range calibration is shown in Figure 8. The AD586, a +5 V precision voltage reference, is an excellent choice for this mode of operation because of its performance, stability and optional fine trim. The AD845 (16 MHz, low power, low cost op amp) is used to maintain the +5 volts under the dynamically changing load conditions of the reference input.

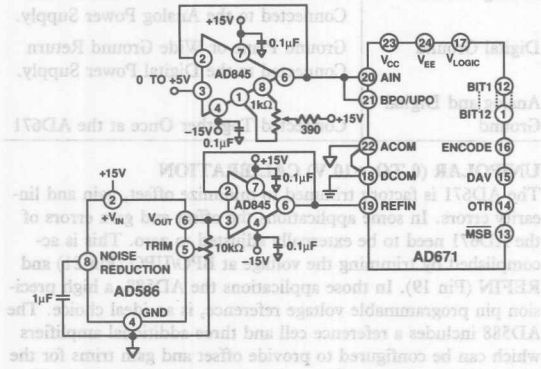

Figure 8. Unipolar (0 to +5 V) Calibration

The AD671 offset error must be trimmed within the analog input path, either directly in front of the AD671 or within the signal conditioning chain, eliminating offset errors induced by the signal conditioning circuitry. Figure 8 shows an example of how the offset error can be trimmed in front of the AD671. The AD586 is configured in the optional fine trim mode to provide +6/−2% (+240/−80 LSBs) of gain trim. The procedure for trimming the offset and gain errors is similar to that used for the unipolar 10 V range with the analog input values set to one-half the 10 V range values.

BIPOLAR (±5 V) CALIBRATION

The connections for the bipolar input range is shown in Figure 9. The AD588 is configured to provide dual +5 V outputs. Providing a +5 V reference voltage for the AD671 gain trim and the +5 V BPO/UPO input for the bipolar offset trim.

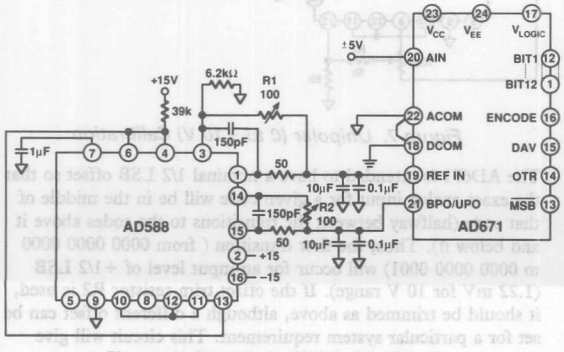

Figure 9. Bipolar (±5 V) Calibration

Bipolar calibration is similar to unipolar calibration. First, a signal 1/2 LSB above negative full scale (−4.9988 V) is applied and R1 is trimmed to give the first transition (0000 0000 0000 to 0000 0000 0001). Then a signal 1 1/2 LSB below positive full scale (+4.9963) is applied, and R2 is trimmed to give the last transition (1111 1111 1110 to 1111 1111 1111).

OUTPUT LATCHES

Figure 10 shows the AD671 connected to the 74HC574 Octal D-type edge triggered latches with 3-state outputs. The latch can drive highly capacitive loads (i.e., bus lines, I/O ports) while maintaining the data signal integrity. The maximum set-up and hold times of the 574 type latch must be less than 20 ns (t_{DD} and t_{SS} minimum). To satisfy the requirements of the 574 type latch the recommended logic families are HC, S, AS, ALS, F or BCT. New data from the AD671 is latched on the rising edge of the DAV (Pin 24) output pulse. Previous data can be latched by inverting the DAV output with a 7404 type inverter. See Figures 20, 21 and 22 for PCB layout recommendations.

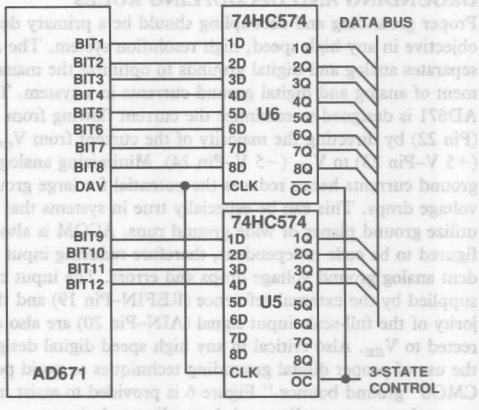

Figure 10. AD671 to Output Latches

OUT OF RANGE

An Out of Range condition exists when the analog input voltage is beyond the input range (0 to +5 V, 0 to +10 V, ±5 V) of the converter. OTR (Pin 14) is set low when the analog input voltage is within the analog input range. OTR is set HIGH and will remain HIGH when the analog input voltage exceeds the input range by typically 1/2 LSB (OTR transition is tested to ±6 LSBs of accuracy) from the center of the ± full-scale output codes. OTR will remain HIGH until the analog input is within the input range and another conversion is completed. By logical ANDing OTR with the MSB and its complement overrange high or underrange low conditions can be detected. Table II is a truth table for the over/under range circuit in Figure 11. Systems requiring programmable gain conditioning prior to the AD671 can immediately detect an out of range condition, thus eliminating gain selection iterations.

Table II. Out of Range Truth Table

OTR	MSB	Analog Input Is
0	0	In Range
0	1	In Range
1	0	Underrange
1	1	Overrange

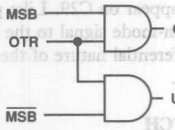

Figure 11. Overrange or Underrange Logic

OUTPUT DATA FORMAT

The AD671 provides both MSB and $\overline{MSB}$ outputs, delivering data in positive true straight binary for unipolar input ranges and positive true offset binary or twos complement for bipolar input ranges. Straight binary coding is used for systems that accept positive-only signals. If straight binary coding is used with bipolar input signals a 0 V input would result in a binary output of 2048. The application software would have to subtract 2048 to determine the true input voltage. Most processors typically perform math on signed integers and assume data is in that format. Twos complement format minimizes software overhead which is especially important in high speed data transfers, such as a DMA operation. The CPU is not bogged down performing data conversion steps, hence increasing the total system throughput.

2

Table III. Output Data Format

Input Range	Coding	Analog Input[1]	Digital Output	OTR[2]
0 to +5 V	Straight Binary	≤−0.00061 V	0000 0000 0000	1

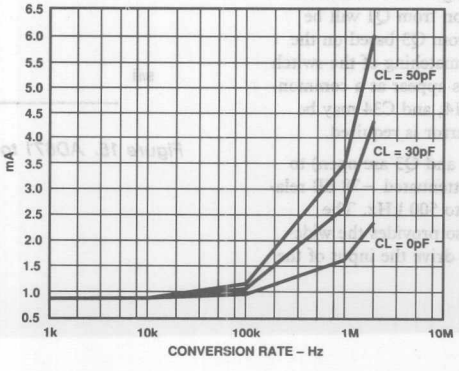

Figure 12. I_{LOGIC} vs. Conversion Rate for Various Capacitive Loads on the Digital Outputs

HIGH PERFORMANCE SAMPLE-AND-HOLD AMPLIFIER (SHA)

In order to take full advantage of the AD671's high speed capabilities, a sample-and-hold amplifier (SHA) with fast acquisition capabilities and rigid accuracy requirements is essential. One possibility is a hybrid SHA such as the HTC-0300A, but often a cost effective alternative like the one shown in Figure 13 may be a better solution. This discrete SHA requires very few components and is able to acquire signals to 0.01% accuracy in less than 350 nanoseconds. Combined with the AD671, signals with bandwidths up to 500 kHz can be converted with 12-bit accuracy.

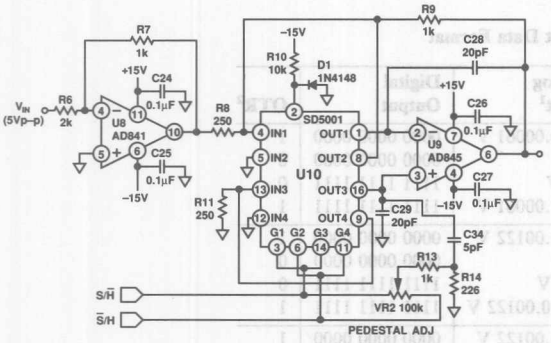

Figure 13. Discrete High Speed Sample-and-Hold Amplifier

CIRCUIT DESCRIPTION

The discrete SHA shown in Figure 13 is a closed-loop, noninverting architecture which accepts 5 V p–p inputs. The overall gain of the SHA is +2 in order to accommodate the 10 V input span of the AD671. The AD841, with a 0.01% settling time of 110 ns, is the suggested input buffer to the SHA. The circuit also employs a SD5001 which contains four ultrahigh speed DMOS switches (Q1–Q4). The high CMRR, low input offset current, and fast settling time of the AD845 op amp are all critical features necessary for optimal performance of the discrete SHA.

In sample mode, Q1 and Q3 of the SD5001 are closed (Q2 and Q4 are open). C28 is charged to the input voltage level at a rate primarily determined by the time constant, R9 · C28. Simultaneously, C29 is connected to ground through a 250 ohm resistor. If C28 is equal to C29, charge injection from Q1 will be approximately equal to charge injection from Q3 based on the symmetry of the circuit and the inherent matching of the switch capacitances. The resultant pedestal errors appear as a common-mode signal to the AD845. VR2, R13, R14, and C34 may be included if further reduction of pedestal error is required.

In hold mode, Q2 and Q4 are closed (Q1 and Q3 are open) to reduce feedthrough. The input signal is attenuated −78 dB relative to the input signal at frequencies up to 500 kHz. The AD845 buffers the voltage on C28 and also provides the wideband, low-impedance output necessary to drive the input of the AD671.

Droop, which occurs as a result of leakage currents, will appear on C28 and will similarly appear on C29. Like pedestal errors, droop appears as a common-mode signal to the AD845 and is greatly reduced by the differential nature of the circuit. Voltage droop is typically 5 µV/µs.

CROSS COUPLED LATCH

As noted in the Theory of Operation, the ENCODE pulse is specified to operate within a window of time. The circuit in Figure 14 can be used to generate a valid ENCODE pulse if a clock pulse width of greater than 30 ns is available.

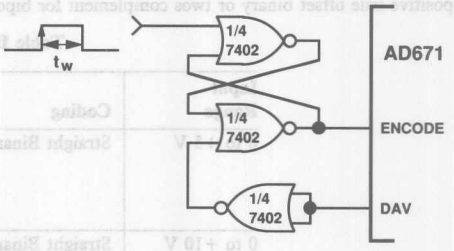

Figure 14. Cross Coupled Latch

TIMING DESCRIPTION

Figure 15 shows the timing requirements for the discrete SHA.

The complementary S/H inputs are HCMOS-compatible although larger gate voltages will improve performance by lowering the on resistances of the DMOS switches. It should be noted that a conversion is started before the SHA has settled to 0.01% accuracy. The discrete SHA takes advantage of the fact that the AD671 does not require a 12-bit accurate input until it is 150 ns into its conversion cycle. See Figures 21, 22 and 23 for PCB layout recommendations.

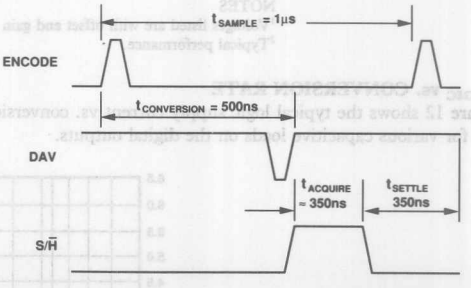

Figure 15. AD671 to Discrete SHA Timing Diagram

DYNAMIC PERFORMANCE

In most sampling applications the dynamic performance of the system is limited by the performance of the SHA. The SHA's dynamic performance can be selected to meet the system sampling requirements. Figures 16 and 17 are typical FFT plots using the discrete SHA in Figure 13.

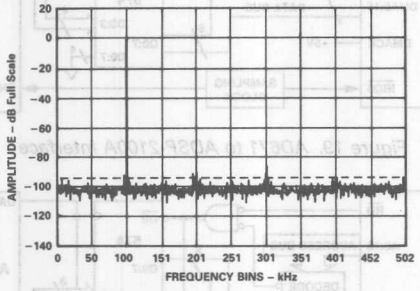

Figure 16. Typical FFT Plot of AD671 and Discrete SHA F_{IN} = 100 kHz

MULTICHANNNEL DATA ACQUISITION SYSTEM

The AD684, a quad high speed sample-and-hold amplifier is ideally suited for multichannel data acquisition applications. Figure 18 shows a typical data acquisition circuit using the AD684 (SHA), ADG201HS (Multiplexer), AD588 (Reference) and the AD671. The AD684 is configured to simultaneously sample four analog inputs. Each held analog input voltage can be selected by the multiplexer and buffered by the AD841. The AD671 is connected in the bipolar input range (±5 V).

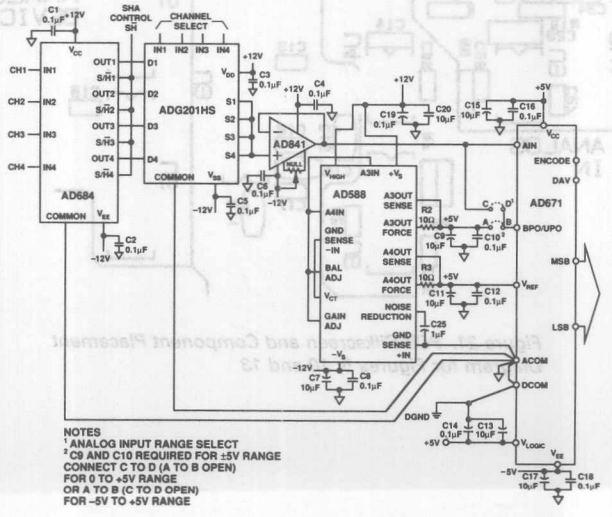

Figure 18. Data Acquisition System Using the AD684 and the AD671

AD671 TO ADSP-2100A INTERFACE

Figure 19 demonstrates the AD671 to ADSP-2100A interface. The 2100A with a clock frequency of 12.5 MHz can execute an instruction in one 80 ns cycle. The AD671 is configured to perform continuous time sampling. The DAV output of the AD671 is asserted at the end of each conversion. DAV can be used to latch the conversion result into the two 574 octal D-latches. The falling edge of the sampling clock is used to generate an interrupt (IRQ3) for the processor. Upon interrupt, the ADSP-2100A starts a data memory read by providing an address on the DMA bus. The decoded address generates OE for the latches and the processor reads their output over the DMA bus. The conversion result is read within a single processor cycle.

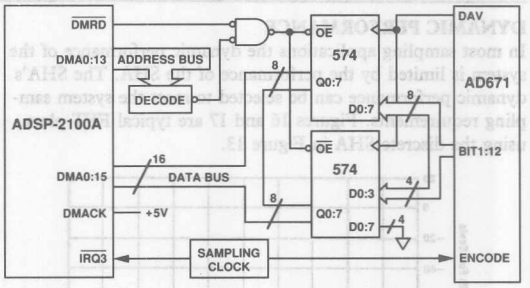

Figure 19. AD671 to ADSP-2100A Interface

AD671 TO ADSP-2101/ADSP-2102 INTERFACE

Figure 20 is identical to the 2100A interface except the sampling clock is used to generate an interrupt (IRQ2) for the processor. Upon interrupt the ADSP-2101A starts a data memory read by providing an address on the Address (A) bus. The decode address generates $\overline{OE}$ for the D-latches and the processor reads their output over the Data (D) bus. Reading the conversion result is thus completed within a single processor cycle.

8-Bit A/D Converter

AD673*

FEATURES

- Complete 8-Bit A/D Converter with Reference, Clock and Comparator
- 30μs Maximum Conversion Time
- Full 8- or 16-Bit Microprocessor Bus Interface
- Unipolar and Bipolar Inputs
- No Missing Codes Over Temperature
- Operates on +5V and −12V to −15V Supplies
- MIL-STD-883 Compliant Version Available

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD673 is a complete 8-bit successive approximation analog-to-digital converter consisting of a DAC, voltage reference, clock, comparator, successive approximation register (SAR) and 3 state output buffers–all fabricated on a single chip. No external components are required to perform a full accuracy 8-bit conversion in 20μs.

The AD673 incorporates advanced integrated circuit design and processing technologies. The successive approximation function is implemented with I^2L (integrated injection logic). Laser trimming of the high stability SiCr thin film resistor ladder network insures high accuracy, which is maintained with a temperature compensated sub-surface Zener reference.

Operating on supplies of +5V and −12V to −15V, the AD673 will accept analog inputs of 0 to +10V or −5V to +5V. The trailing edge of a positive pulse on the CONVERT line initiates the 20μs conversion cycle. $\overline{\text{DATA READY}}$ indicates completion of the conversion.

The AD673 is available in two versions. The AD673J as specified over the 0 to +70°C temperature range and the AD673S guarantees ±½LSB relative accuracy and no missing codes from −55°C to +125°C.

Two package configurations are offered. All versions are also offered in a 20-pin hermetically sealed ceramic DIP. The AD673J is also available in a 20-pin plastic DIP.

PRODUCT HIGHLIGHTS

1. The AD673 is a complete 8-bit A/D converter. No external components are required to perform a conversion.
2. The AD673 interfaces to many popular microprocessors without external buffers or peripheral interface adapters.
3. The device offers true 8-bit accuracy and exhibits no missing codes over its entire operating temperature range.
4. The AD673 adapts to either unipolar (0 to +10V) or bipolar (−5V to +5V) analog inputs by simply grounding or opening a single pin.
5. Performance is guaranteed with +5V and −12V or −15V supplies.
6. The AD673 is available in a version compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD673/883B data sheet for detailed specifications.

NOTES

[1]Relative accuracy is defined as the deviation of the code transition points from the ideal transfer point on a straight line from the zero to the full scale of the device.

[2]Full scale calibration is guaranteed trimmable to zero with an external 200Ω potentiometer in place of the 15Ω fixed resistor.
Full scale is defined as 10 volts minus 1LSB, or 9.961 volts.

[3]Defined as the resolution for which no missing codes will occur.

[4]The data output lines have active pull-ups to source 0.5mA. The DATA READY line is open collector with a nominal 6kΩ internal pull-up resistor.

Specifications subject to change without notice.

Specifications shown in boldface are tested on all production units at final electrical test. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested on all production units.

ABSOLUTE MAXIMUM RATINGS

FUNCTIONAL DESCRIPTION

A block diagram of the AD673 is shown in Figure 1. The positive CONVERT pulse must be at least 500ns wide. $\overline{DR}$ goes high within 1.5μs after the leading edge of the convert pulse indicating that the internal logic has been reset. The negative edge of the CONVERT pulse initiates the conversion. The internal 8-bit current output DAC is sequenced by the integrated injection logic (I^2L) successive approximation register (SAR) from its most significant bit to least significant bit to provide an output current which accurately balances the input signal current through the 5kΩ resistor. The comparator determines whether the addition of each successively weighted bit current causes the DAC current sum to be greater or less than the input current; if the sum is more, the bit is turned off. After testing all bits, the SAR contains a 8-bit binary code which accurately represents the input signal to within (0.05% of full scale).

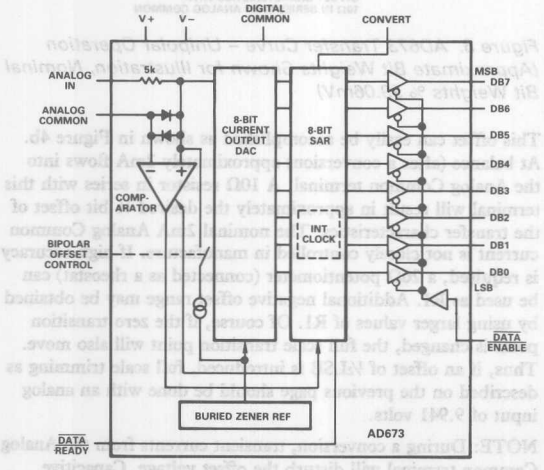

Figure 1. AD673 Functional Block Diagram

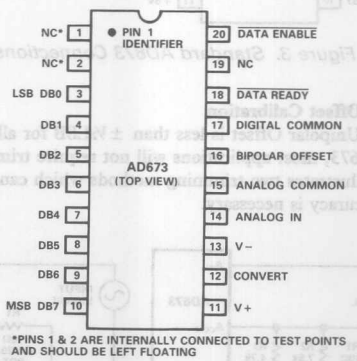

The SAR drives $\overline{DR}$ low to indicate that the conversion is complete and that the data is available to the output buffers. $\overline{DATA\ ENABLE}$ can then be activated to enable the 8-bits of data desired. $\overline{DATA\ ENABLE}$ should be brought high prior to the next conversion to place the output buffers in the high impedance state.

The temperature compensated buried Zener reference provides the primary voltage reference to the DAC and ensures excellent stability with both time and temperature. The bipolar offset input controls a switch which allows the positive bipolar offset current (exactly equal to the value of the MSB less ½LSB) to be injected into the summing (+) node of the comparator to offset the DAC output. Thus the nominal 0 to +10V unipolar input range becomes a −5V to +5V range. The 5kΩ thin film input resistor is trimmed so that with a full scale input signal, an input current will be generated which exactly matches the DAC output with all bits on.

UNIPOLAR CONNECTION

The AD673 contains all the active components required to perform a complete A/D conversion. Thus, for many applications, all that is necessary is connection of the power supplies (+5V and −12V to −15V), the analog input and the convert pulse. However, there are some features and special connections which should be considered for achieving optimum performance. The functional pin-out is shown in Figure 2.

The standard unipolar 0 to +10V range is obtained by shorting the bipolar offset control pin (pin 16) to digital common (pin 17).

*PINS 1 & 2 ARE INTERNALLY CONNECTED TO TEST POINTS AND SHOULD BE LEFT FLOATING

Figure 2. AD673 Pin Connections

Full Scale Calibration

The 5kΩ thin film input resistor is laser trimmed to produce a current which matches the full scale current of the internal DAC–plus about 0.3%–when an analog input voltage of 9.961 volts (10 volts – 1LSB) is applied at the input. The input resistor is trimmed in this way so that if a fine trimming potentiometer is inserted in series with the input signal, the input current at the full scale input voltage can be trimmed down to match the DAC full scale current as precisely as desired. However, for many applications the nominal 9.961 volt full scale can be achieved to sufficient accuracy by simply inserting a 15Ω resistor in series with the analog input to pin 14. Typical full scale calibration error will then be within ±2LSB or ±0.8%. If more precise calibration is desired, a 200Ω trimmer should be used instead. Set the analog input at 9.961 volts, and set the trimmer so that the output code is just at the transition between 111111 10 and 11111111. Each LSB will then have a weight of 39.06mV. If a nominal full scale of 10.24 volts is desired (which makes the LSB have a weight of exactly 40.0mV), a 100Ω resistor and a 100Ω trimmer (or a 200Ω trimmer with good resolution) should be used. Of course, larger full scale ranges can be arranged by using a larger input resistor, but linearity and full scale temperature coefficient may be compromised if the external resistor becomes a sizeable percentage of 5kΩ. Figure 3 illustrates the connections required for full scale calibration.

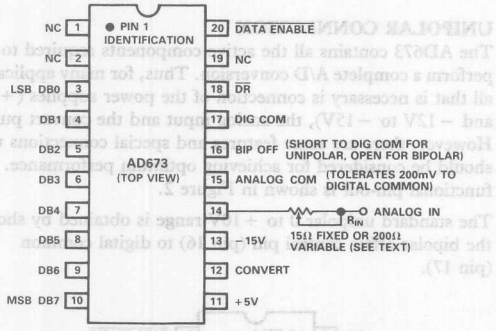

Figure 3. Standard AD673 Connections

Unipolar Offset Calibration

Since the Unipolar Offset is less than ±½LSB for all versions of the AD673, most applications will not require trimming. Figure 4 illustrates two trimming methods which can be used if greater accuracy is necessary.

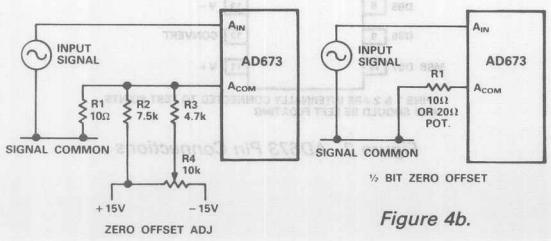

Figure 4a.

Figure 4b.

Figure 4. Unipolar Offset Trimming

Figure 4a shows how the converter zero may be offset to correct for initial offset and/or input signal offsets. As shown, the circuit gives approximately symmetrical adjustment in unipolar mode.

Figure 5 shows the nominal transfer curve near zero for an AD673 in unipolar mode. The code transitions are at the edges of the nominal bit weights. In some applications it will be preferable to offset the code transitions so that they fall between the nominal bit weights, as shown in the offset characteristics.

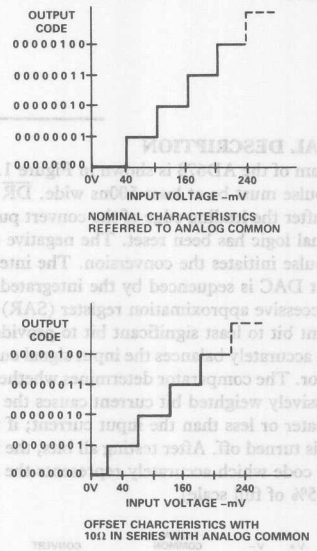

Figure 5. AD673 Transfer Curve – Unipolar Operation (Approximate Bit Weights Shown for Illustration, Nominal Bit Weights % 39.06mV)

This offset can easily be accomplished as shown in Figure 4b. At balance (after a conversion) approximately 2mA flows into the Analog Common terminal. A 10Ω resistor in series with this terminal will result in approximately the desired ½ bit offset of the transfer characteristics. The nominal 2mA Analog Common current is not closely controlled in manufacture. If high accuracy is required, a 20Ω potentiometer (connected as a rheostat) can be used as R1. Additional negative offset range may be obtained by using larger values of R1. Of course, if the zero transition point is changed, the full scale transition point will also move. Thus, if an offset of ½LSB is introduced, full scale trimming as described on the previous page should be done with an analog input of 9.941 volts.

NOTE: During a conversion, transient currents from the Analog Common terminal will disturb the offset voltage. Capacitive decoupling should not be used around the offset network. These transients will settle appropriately during a conversion. Capacitive decoupling will "pump up" and fail to settle resulting in conversion errors. Power supply decoupling, which returns to analog signal common, should go to the signal input side of the resistive offset network.

BIPOLAR CONNECTION

To obtain the bipolar −5V to +5V range with an offset binary output code, the bipolar offset control pin is left open.

A −5.00 volt signal will give a 8-bit code of 00000000; an input of 0.00 volts results in an output code of 10000000 and +4.961 volts at the input yields the 11111111 code. The nominal transfer curve is shown in Figure 6.

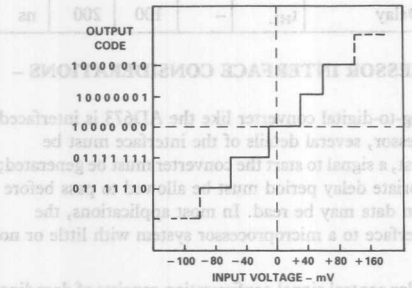

Figure 6. AD673 Transfer Curve–Bipolar Operation

Note that in the bipolar mode, the code transitions are offset ¼LSB such that an input voltage of 0 volts −5mV to +35mV yields the code representing zero (10000000). Each output code is then *centered* on its nominal input voltage.

Full Scale Calibration

Full Scale Calibration is accomplished in the same manner as in Unipolar operation except the full scale input voltage is +4.61 volts.

Negative Full Scale Calibration

The circuit in Figure 4a can also be used in Bipolar operation to offset the input voltage (nominally −5V) which results in the 000000 00 code. R2 should be omitted to obtain a symmetrical range.

The bipolar offset control input is not directly TTL compatible but a TTL interface for logic control can be constructed as shown in Figure 7.

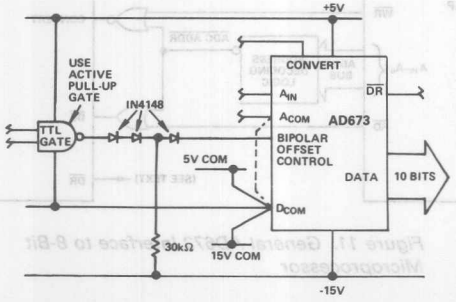

Figure 7. Bipolar Offset Controlled by Logic Gate
Gate Output = 1 Unipolar 0–10V Input Range
Gate Output = 0 Bipolar ±5V Input Range

SAMPLE-HOLD AMPLIFIER CONNECTION TO THE AD673

Many situations in high-speed acquisition systems or digitizing rapidly changing signals require a sample-hold amplifier (SHA) in front of the A-D converter. The SHA can acquire and hold a signal faster than the converter can perform a conversion. A SHA can also be used to accurately define the exact point in time at which the signal is sampled. For the AD673, a SHA can also serve as a high input impedance buffer.

Figure 8 shows the AD673 connected to the AD582 monolithic SHA for high speed signal acquisition. In this configuration, the AD582 will acquire a 10 volt signal in less than 10μs with a droop rate less than 100μV/ms.

$\overline{DR}$ goes high after the conversion is initiated to indicate that reset of the SAR is complete. In Figure 8 it is also used to put the AD582 into the hold mode while the AD673 begins its conversion cycle. (The AD582 settles to final value well in advance of the first comparator decision inside the AD673).

$\overline{DR}$ goes low when the conversion is complete placing the AD582 back in the sample mode. Configured as shown in Figure 8, the next conversion can be initiated after a 10μs delay to allow for signal acquisition by the AD582.

Observe carefully the ground, supply, and bypass capacitor connections between the two devices. This will minimize ground noise and interference during the conversion cycle.

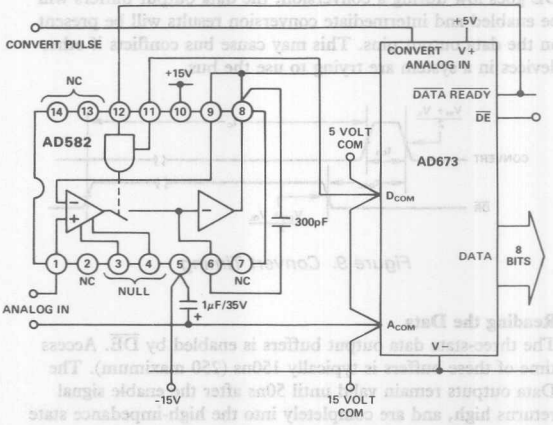

Figure 8. Sample-Hold Interface to the AD673

GROUNDING CONSIDERATIONS

The AD673 provides separate Analog and Digital Common connections. The circuit will operate properly with as much as ±200mV of common mode voltage between the two commons. This permits more flexible control of system common bussing and digital and analog returns.

In normal operation, the Analog Common terminal may generate transient currents of up to 2mA during a conversion. In addition a static current of about 2mA will flow into Analog Common in the unipolar mode after a conversion is complete. The Analog Common current will be modulated by the variations in input signal.

The absolute maximum voltage rating between the two commons is ±1 volt. It is recommended that a parallel pair of back-to-back protection diodes be connected between the commons if they are not connected locally.

CONTROL AND TIMING OF THE AD673

The operation of the AD673 is controlled by two inputs: CONVERT and $\overline{\text{DATA ENABLE}}$.

Starting a Conversion

The conversion cycle is initiated by a positive-going CONVERT pulse at least 500ns wide. The rising edge of this pulse resets the internal logic, clears the result of the previous conversion, and sets $\overline{\text{DR}}$ high. The falling edge of CONVERT begins the conversion cycle. When conversion is completed $\overline{\text{DR}}$ returns low. During the conversion cycle, $\overline{\text{DE}}$ should be held high. If $\overline{\text{DE}}$ goes low during a conversion, the data output buffers will be enabled and intermediate conversion results will be present on the data output pins. This may cause bus conflicts if other devices in a system are trying to use the bus.

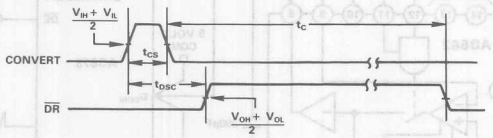

Figure 9. Convert Timing

Reading the Data

The three-state data output buffers is enabled by $\overline{\text{DE}}$. Access time of these buffers is typically 150ns (250 maximum). The Data outputs remain valid until 50ns after the enable signal returns high, and are completely into the high-impedance state 100ns later.

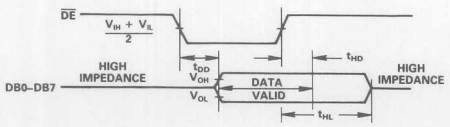

Figure 10. Read Timing

TIMING SPECIFICATIONS

Parameter	Symbol	Min	Typ	Max	Units
CONVERT Pulse Width	t_{CS}	500	–	–	ns
$\overline{\text{DR}}$ Delay from CONVERT	t_{DSC}	–	1	1.5	µs
Conversion Time	t_C	10	20	30	µs
Data Access Time	t_{DD}	0	150	250	ns
Data Valid after $\overline{\text{DE}}$ High	t_{HD}	50	–	–	ns
Output Float Delay	t_{HL}	–	100	200	ns

MICROPROCESSOR INTERFACE CONSIDERATIONS – GENERAL

When an analog-to-digital converter like the AD673 is interfaced to a microprocessor, several details of the interface must be considered. First, a signal to start the converter must be generated; then an appropriate delay period must be allowed to pass before valid conversion data may be read. In most applications, the AD673 can interface to a microprocessor system with little or no external logic.

The most popular control signal configuration consists of decoding the address assigned to the AD673, then gating this signal with the system's WR signal to generate the CONVERT pulse, and gating it with RD to enable the output buffers. The use of a memory address and memory WR and RD signals denotes "memory-mapped" I/O interfacing, while the use of a separate I/O address space denotes "isolated I/O" interfacing.

Figure 11 shows a generalized diagram of the control logic for an AD673 interfaced to an 8-bit data bus, where an address ADC ADDR has been decoded. ADC ADDR starts the converter when written to (the actual data being written to the converter does not matter) and contains the high byte data during read operations.

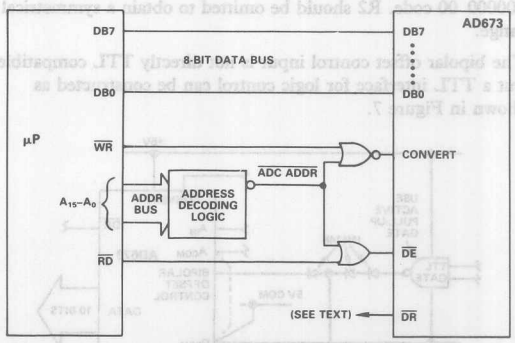

Figure 11. General AD673 Interface to 8-Bit Microprocessor

In systems where this read-write interface is used, at least 30 microseconds (the maximum conversion time) must be allowed to pass between starting a conversion and reading the results. This delay or "timeout" period can be implemented in a short software routine such as a countdown loop, enough dummy instructions to consume 30 microseconds, or enough actual useful instructions to consume the required time. In tightly-timed systems, the $\overline{DR}$ line may be read through an external three-state buffer to determine precisely when a conversion is complete. Higher-speed systems may choose to use $\overline{DR}$ to signal an interrupt to the processor at the end of a conversion.

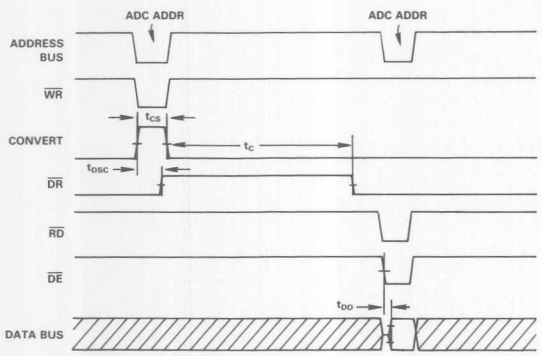

Figure 12. Typical AD673 Timing Diagram

CONVERT Pulse Generation

The AD673 is tested with a CONVERT pulse width of 500ns and will typically operate with a pulse as short as 300ns. However, some microprocessors produce active WR pulses which are shorter than this. Either of the circuits shown in Figure 13 can be used to generate an adequate CONVERT pulse for the AD673. In both circuits, the short low-going WR pulse sets the CONVERT line high through a flip-flop. The rising edge of $\overline{DR}$ (which signifies that the internal logic has been reset) resets the flip-flop and brings CONVERT low, which starts the conversion.

Note that t_{DSC} is slightly longer when the result of the previous conversion contains a logic 1 on the LSB. This means that the actual CONVERT pulse generated by the circuits in Figure 13 will vary slightly in width.

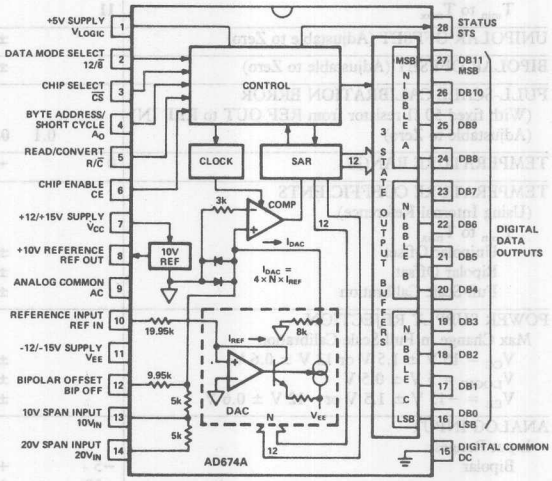
12-Bit A/D Converter



AD674A*

FEATURES

Complete 12-Bit A/D Converter with Reference and Clock
Faster Version of AD574A
8- and 16-Bit Bus Interface
No Missing Codes Over Temperature
15 μs max Conversion Time
±12 V and ±15 V Operation
Unipolar and Bipolar Inputs

NOT RECOMMENDED FOR NEW DESIGNS, REPLACE WITH AD674B (SEE PAGE 2–109)

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD674A is a complete 12-bit successive-approximation analog-to-digital converter with three-state output buffer circuitry for direct interface to an 8- and 16-bit microprocessor bus. A high-precision voltage reference and clock are included on-chip, and the circuit requires only power supplies and control signals for operation.

The AD674A is pin compatible with the industry-standard AD574A but offers faster conversion time and bus-access speed.

The AD674A design is implemented with two LSI chips each containing both analog and digital circuitry, resulting in the maximum performance and flexibility at the lowest cost. The chips are laser trimmed at the wafer stage to obtain full rated performance without external trims.

The AD674A is available in six different grades. The AD674AJ, K, and L grades are specified for operation over the 0 to +70°C temperature range. The AD674AS, T, and U are specified for the −55°C to +125°C range. All grades are available in a 28-pin hermetically sealed ceramic DIP.

The S, T, and U grades are also available with optional processing to MIL-STD-883C, Class B in a 28-pin DIP or 28-pin LCC package. The Analog Devices Military Products Databook should be consulted for details on /883B testing of the AD674A.

***Protected by U.S. Patent Nos. 3,803,590; 4,213,806; 4,511,413; RE 28,633.**

This an abridged version of the data sheet. To obtain a complete data sheet, contact your nearest sales office.

PRODUCT HIGHLIGHTS

1. The AD674A interfaces to most 8- or 16-bit microprocessors. Multiple-mode three-state output buffers connect directly to the data bus while the read and convert commands are taken from the control bus. The 12 bits of output data can be read either as one 12-bit word or as two 8-bit bytes (one with 8 data bits, the other with 4 data bits and 4 trailing zeroes).
2. The precision, laser-trimmed scaling and bipolar offset resistors provide four calibrated ranges: 0 to +10 and 0 to +20 volts unipolar, −5 to +5 and −10 to +10 volts bipolar. Typical bipolar offset and full-scale calibration errors of ±0.1% can be trimmed to zero with one external component each.
3. The internal buried Zener reference is trimmed to 10.00 volts with 1% maximum error and 15 ppm/°C typical T.C. The reference is available externally and can drive up to 2.0 mA beyond the requirements of the reference and bipolar offset resistors.

Complete 12-Bit A/D Converters

AD674B*/AD774B*

FEATURES

Complete Monolithic 12-Bit A/D Converters with Reference, Clock, and Three-State Output Buffers
Industry Standard Pinout
High Speed Upgrades for AD574A
8- and 16-Bit Microprocessor Interface
8 μs (max) Conversion Time (AD774B)
15 μs (max) Conversion Time (AD674B)
±5 V, ±10 V, 0–10 V, 0–20 V Input Ranges
Commercial, Industrial and Military Temperature Range Grades
MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD674B and AD774B are complete 12-bit successive-approximation analog-to-digital converters with three-state output buffer circuitry for direct interface to 8- and 16-bit microprocessor busses. A high precision voltage reference and clock are included on chip, and the circuit requires only power supplies and control signals for operation.

The AD674B and AD774B are pin compatible with the industry-standard AD574A, but offer faster conversion time and bus-access speed than the AD574A and lower power consumption. The AD674B converts in 15 μs (maximum) and the AD774B converts in 8 μs (maximum).

The monolithic design is implemented using Analog Devices' BiMOS II process allowing high performance bipolar analog circuitry to be combined on the same die with digital CMOS logic. Offset, linearity and scaling errors are minimized by active laser-trimming of thin-film resistors.

Five different grades are available. The J and K grades are specified for operation over the 0°C to +70°C temperature range. The A and B grades are specified from −40°C to +85°C, the T grade is specified from −55°C to +125°C. The J and K grades are available in a 28-pin plastic DIP or 28-lead SOIC. All other grades are available in a 28-pin hermetically sealed ceramic DIP.

PRODUCT HIGHLIGHTS

1. Industry Standard Pinout: The AD674B and AD774B utilize the pinout established by the industry standard AD574A.
2. Analog Operation: The precision, laser-trimmed scaling and bipolar offset resistors provide four calibrated ranges: 0 to +10 V and 0 to +20 V unipolar; −5 V to +5 V and −10 V to +10 V bipolar. The AD674B and AD774B operate on +5 V and ±12 V or ±15 V power supplies.
3. Flexible Digital Interface: On-chip multiple-mode three-state output buffers and interface logic allow direct connection to most microprocessors. The 12 bits of output data can be read either as one 12-bit word or as two 8-bit bytes (one with 8 data bits, the other with 4 data bits and 4 trailing zeros).
4. The internal reference is trimmed to 10.00 volts with 1% maximum error and 10 ppm/°C typical temperature coefficient. The reference is available externally and can drive up to 2.0 mA beyond the requirements of the converter and bipolar offset resistors.
5. The AD674B and AD774B are available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD674B/AD774B/883B data sheet for detailed specifications.

*Protected by U.S. Patent Nos. 4,250,445; 4,808,908; RE30586.

NOTES

[1] t_{DD} is measured with the load circuit of Figure 3a and is defined as the time required for an output to cross 0.4 V or 2.4 V.

[2] 0°C to T_{MAX}.

[3] At −40°C.

[4] At −55°C.

[5] t_{HL} is defined as the time required for the data lines to change 0.5 V when loaded with the circuit of Figure 3b.

Specifications shown in **boldface** are tested on all devices at final electrical test with worst case supply voltages at T_{MIN}, +25°C, and T_{MAX}. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested.

Specifications subject to change without notice.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

DEFINITION OF SPECIFICATIONS

LINEARITY ERROR

Linearity error refers to the deviation of each individual code from a line drawn from "zero" through "full scale." The point used as "zero" occurs 1/2 LSB (1.22 mV for 10 volt span) before the first code transition (all zeroes to only the LSB "on"). "Full scale" is defined as a level 1 1/2 LSB beyond the last code transition (to all ones). The deviation of a code from the true straight line is measured from the middle of each particular code.

The K, B, and T grades are guaranteed for maximum nonlinearity of ±1/2 LSB. For these grades, this means that an analog value which falls exactly in the center of a given code width will result in the correct digital output code. Values nearer the upper or lower transition of the code width may produce the next upper or lower digital output code. The J and A grades are guaranteed to ±1 LSB max error. For these grades, an analog value which falls within a given code width will result in either the correct code for that region or either adjacent one.

Note that the linearity error is not user adjustable.

DIFFERENTIAL LINEARITY ERROR (NO MISSING CODES)

A specification which guarantees no missing codes requires that every code combination appear in a monotonic increasing sequence as the analog input level is increased. Thus every code must have a finite width. The AD674B and AD774B guarantee no missing codes to 12-bit resolution, requiring that all 4096 codes must be present over the entire operating temperature ranges.

UNIPOLAR OFFSET

The first transition should occur at a level 1/2 LSB above analog common. Unipolar offset is defined as the deviation of the actual transition from that point. This offset can be adjusted as discussed later. The unipolar offset temperature coefficient specifies the maximum change of the transition point over temperature, with or without external adjustment.

BIPOLAR OFFSET

In the bipolar mode the major carry transition (0111 1111 1111 to 1000 0000 0000) should occur for an analog value 1/2 LSB below analog common. The bipolar offset error and temperature coefficient specify the initial deviation and maximum change in the error over temperature.

QUANTIZATION UNCERTAINTY

Analog-to-digital converters exhibit an inherent quantization uncertainty of ±1/2 LSB. This uncertainty is a fundamental characteristic of the quantization process and cannot be reduced for a converter of given resolution.

LEFT-JUSTIFIED DATA

The output data format is left-justified. This means that the data represents the analog input as a fraction of full scale, ranging from 0 to 4095/4096. This implies a binary point 4095 to the left of the MSB.

FULL-SCALE CALIBRATION ERROR

The last transition (from 1111 1111 1110 to 1111 1111 1111) should occur for an analog value 1 1/2 LSB below the nominal full scale (9.9963 volts for 10.000 volts full scale). The full-scale calibration error is the deviation of the actual level at the last transition from the ideal level. This error, which is typically 0.05 to 0.1% of full scale, can be trimmed out as shown in Figures 7 and 8. The full-scale calibration error over temperature is given with and without the initial error trimmed out. The temperature coefficients for each grade indicate the maximum change in the full-scale gain from the initial value using the internal 10 V reference.

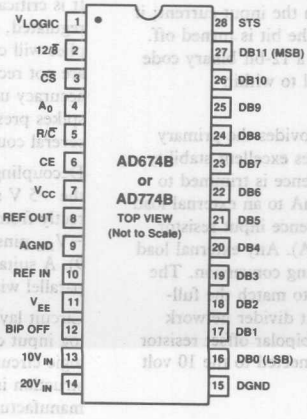
TEMPERATURE DRIFT

The temperature drift for full-scale calibration, unipolar offset, and bipolar offset specifies the maximum change from the initial (+25°C) value to the value at T_{MIN} or T_{MAX}.

POWER SUPPLY REJECTION

The standard specifications assume use of +5.00 V and ±15.00 V or ±12.00 V supplies. The only effect of power supply error on the performance of the device will be a small change in the full-scale calibration. This will result in a linear change in all lower-order codes. The specifications show the maximum full-scale change from the initial value with the supplies at the various limits.

CODE WIDTH



A fundamental quantity for A/D converter specifications is the code width. This is defined as the range of analog input values for which a given digital output code will occur. The nominal value of a code width is equivalent to 1 least significant bit (LSB) of the full-scale range or 2.44 mV out of 10 volts for a 12-bit ADC.

AD674B AND AD774B PIN DESCRIPTION

Symbol	Pin No.	Type	Name and Function
AGND	9	P	Analog Ground (Common).
A_0	4	DI	Byte Address/Short Cycle. If a conversion is started with A_0 Active LOW, a full 12-bit conversion cycle is initiated. If A_0 is Active HIGH during a convert start, a shorter 8-bit conversion cycle results. During Read (R/$\overline{C}$ = 1) with 12/$\overline{8}$ LOW, A_0 = LOW enables the 8 most significant bits, and A_0 = HIGH enables DB3–DB0 and sets DB7–DB4 = 0.
BIP OFF	12	AI	Bipolar Offset. Connect through a 50 Ω resistor to REF OUT for bipolar operation or to Analog Common for unipolar operation.
CE	6	DI	Chip Enable. Chip Enable is Active HIGH and is used to initiate a convert or read operation.
$\overline{CS}$	3	DI	Chip Select. Chip Select is Active LOW.
DB11–DB8	27–24	DO	Data Bits 11 through 8. In the 12-bit format (see 12/$\overline{8}$ and A_0 pins), these pins provide the upper 4 bits of data. In the 8-bit format, they provide the upper 4 bits when A_0 is LOW and are disabled when A_0 is HIGH.
DB7–DB4	23–20	DO	Data Bits 7 through 4. In the 12-bit format these pins provide the middle 4 bits of data. In the 8-bit format they provide the middle 4 bits when A_0 is LOW and all zeroes when A_0 is HIGH.
DB3–DB0	19–16	DO	Data Bits 3 through 0. In both the 12-bit and 8-bit format these pins provide the lower 4 bits of data when A_0 is HIGH; they are disabled when A_0 is LOW.
DGND	15	P	Digital Ground (Common).
REF OUT	8	AO	+10 V Reference Output.
R/$\overline{C}$	5	DI	Read/Convert. In the full control mode R/$\overline{C}$ is Active HIGH for a read operation and Active LOW for a convert operation. In the stand-alone mode, the falling edge of R/$\overline{C}$ initiates a conversion.
REF IN	10	AI	Reference Input is connected through a 50 Ω resistor to +10 V Reference for normal operation.
STS	28	DO	Status is Active HIGH when a conversion is in progress and goes LOW when the conversion is completed.
V_{CC}	7	P	+12 V/+15 V Analog Supply.
V_{EE}	11	P	−12 V/−15 V Analog Supply.
V_{LOGIC}	1	P	+5 V Logic Supply.
10 V_{IN}	13	AI	10 V Span Input, 0 to +10 V unipolar mode or −5 V to +5 V bipolar mode. When using the 20 V Span, 10 V_{IN} should not be connected.
20 V_{IN}	14	AI	20 V Span Input, 0 to +20 V unipolar mode or −10 V to +10 V bipolar mode. When using the 10 V Span, 20 V_{IN} should not be connected.
12/$\overline{8}$	2	DI	The 12/$\overline{8}$ pin determines whether the digital output data is to be organized as two 8-bit words (12/$\overline{8}$ LOW) or a single 12-bit word (12/$\overline{8}$ HIGH).

PIN CONFIGURATION

CIRCUIT OPERATION

The AD674B and AD774B are complete 12-bit monolithic A/D converters which require no external components to provide the complete successive-approximation analog-to-digital conversion function. A block diagram is shown in Figure 5.

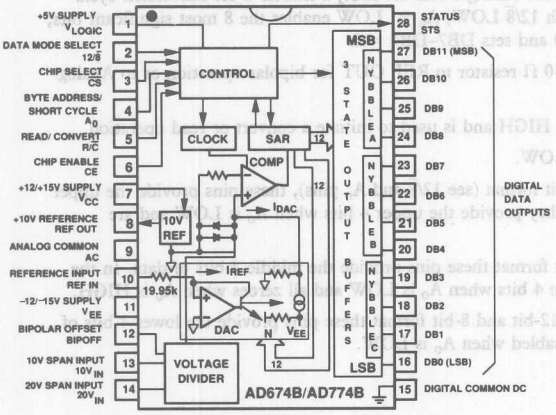

Figure 5. Block Diagram of AD674B and AD774B

When the control section is commanded to initiate a conversion (as described later), it enables the clock and resets the successive-approximation register (SAR) to all zeroes. Once a conversion cycle has begun, it cannot be stopped or restarted and data is not available from the output buffers. The SAR, timed by the clock, will sequence through the conversion cycle and return an end-of-convert flag to the control section. The control section will then disable the clock, bring the output status flag low, and enable control functions to allow data read by external command.

During the conversion cycle, the internal 12-bit current output DAC is sequenced by the SAR from the most-significant-bit (MSB) to least-significant-bit (LSB) to provide an output current which accurately balances the input signal current through the divider network. The comparator determines whether the addition of each successively-weighted bit current causes the DAC current sum to be greater or less than the input current; if the sum is less, the bit is left on; if more, the bit is turned off. After testing all the bits, the SAR contains a 12-bit binary code which accurately represents the input signal to within ±1/2 LSB.

The temperature-compensated reference provides the primary voltage reference to the DAC and guarantees excellent stability with both time and temperature. The reference is trimmed to 10.00 volts ±1%; it can supply up to 2.0 mA to an external load in addition to the requirements of the reference input resistor (0.5 mA) and bipolar offset resistor (0.5 mA). Any external load on the reference must remain constant during conversion. The thin film application resistors are trimmed to match the full-scale output current of the DAC. The input divider network provides a 10 V or 20 V input range. The bipolar offset resistor is grounded for unipolar operation and connected to the 10 volt reference for bipolar operation.

DRIVING THE ANALOG INPUT

The AD674B and AD774B are successive-approximation analog-to-digital converters. During the conversion cycle, the ADC input current is modulated by the DAC test current at approximately a 1 MHz rate. Thus it is important to recognize that the signal source driving the ADC must be capable of holding a constant output voltage under dynamically-changing load conditions.

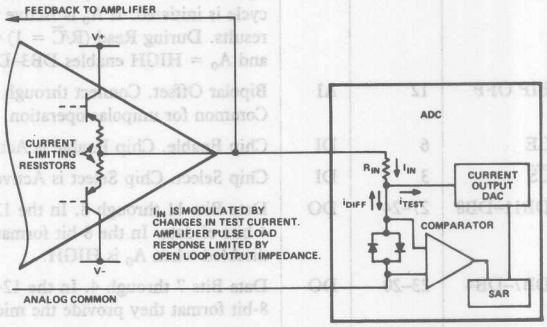

Figure 6. Op Amp–ADC Interface

The closed-loop output impedance of an op amp is equal to the open-loop output impedance (usually a few hundred ohms) divided by the loop gain at the frequency of interest. It is often assumed that the loop gain of a follower-connected op amp is sufficiently high to reduce the closed-loop output impedance to a negligibly small value, particularly if the signal is low frequency. However, the amplifier driving the ADC must either have sufficient loop gain at 1 MHz to reduce the closed-loop output impedance to a low value or have low open-loop output impedance. This can be accomplished by using a wideband op amp, such as the AD711.

If a sample-hold amplifier is required, the monolithic AD585 or AD781 is recommended, with the output buffer driving the AD674B or AD774B input directly. A better alternative is the AD1674 which is a 10 μs *sampling* ADC in the same pinout as the AD574A, AD674A or AD774B and is functionally equivalent.

SUPPLY DECOUPLING AND LAYOUT CONSIDERATIONS

It is critically important that the power supplies be filtered, well regulated, and free from high frequency noise. Use of noisy supplies will cause unstable output codes. Switching power supplies are not recommended for circuits attempting to achieve 12-bit accuracy unless great care is used in filtering any switching spikes present in the output. Few millivolts of noise represent several counts of error in a 12-bit ADC.

Decoupling capacitors should be used on all power supply pins; the +5 V supply decoupling capacitor should be connected directly from Pin 1 to Pin 15 (digital common) and the $+V_{CC}$ and $-V_{EE}$ pins should be decoupled directly to analog common (Pin 9). A suitable decoupling capacitor is a 4.7 μF tantalum type in parallel with a 0.1 μF ceramic disc type.

Circuit layout should attempt to locate the ADC, associated analog input circuitry, and interconnections as far as possible from logic circuitry. For this reason, the use of wire-wrap circuit construction is not recommended. Careful printed-circuit layout and manufacturing is preferred.

UNIPOLAR RANGE CONNECTIONS FOR THE AD674B and AD774B

The AD674B and AD774B contain all the active components required to perform a complete 12-bit A/D conversion. Thus, for most situations, all that is necessary is connection of the power supplies (+5 V, +12/+15 V and −12/−15 V), the analog input, and the conversion initiation command, as discussed on the next page.

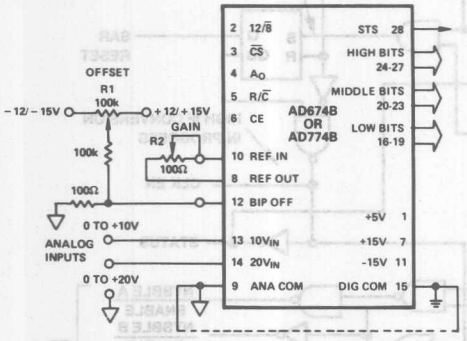

Figure 7. Unipolar Input Connections

All of the thin-film application resistors of the AD674B and AD774B are factory trimmed for absolute calibration. Therefore, in many applications, no calibration trimming will be required. The absolute accuracy for each grade is given in the specification tables. For example, if no trims are used, ±2 LSB max zero offset error and ±0.25% (10LSB) max full-scale error are guaranteed. If the offset trim is not required, Pin 12 can be connected directly to Pin 9; the two resistors and trimmer for Pin 12 are then not needed. If the full-scale trim is not required, a 50 Ω 1% metal film resistor should be connected between Pin 8 and Pin 10.

The analog input is connected between Pins 13 and 9 for a 0 to +10 V input range, between Pins 14 and 9 for a 0 to +20 V input range. Input signals beyond the supplies are easily accommodated. For the 10 volt span input, the LSB has a nominal value of 2.44 mV; for the 20 volt span, 4.88 mV. If a 10.24 V range is desired (nominal 2.5 mV/bit), the gain trimmer (R2) should be replaced by a 50 Ω resistor, and a 200 Ω trimmer inserted in series with the analog input to Pin 13 (for a full-scale range of 20.48 V (5 mV/bit), use a 500 Ω trimmer into Pin 14). The gain trim described below is now done with these trimmers. The nominal input impedance into Pin 13 is 5 kΩ, and 10 kΩ into Pin 14.

UNIPOLAR CALIBRATION

The connections for unipolar ranges are shown in Figure 7. The AD674B or AD774B is trimmed to a nominal 1/2 LSB offset so that the exact analog input for a given code will be in the middle of that code (halfway between the transitions to the codes above and below it). Thus, when properly calibrated, the first transition (from 0000 0000 0000 to 0000 0000 0001) will occur for an input level of +1/2 LSB (1.22 mV for 10 V range).

If Pin 12 is connected to Pin 9, the unit will behave in this manner, within specifications. If the offset trim (R1) is used, it should be trimmed as above, although a different offset can be set for a particular system requirement. This circuit will give approximately ±15 mV of offset trim range.

The full-scale trim is done by applying a signal 1 1/2 LSB below the nominal full scale (9.9963 for a 10 V range). Trim R2 to give the last transition (1111 1111 1110 to 1111 1111 1111).

BIPOLAR OPERATION

The connections for bipolar ranges are shown in Figure 8. Again, as for the unipolar ranges, if the offset and gain specifications are sufficient, one or both of the trimmers shown can be replaced by a 50 Ω ±1% fixed resistor. The analog input is applied as for the unipolar ranges. Bipolar calibration is similar to unipolar calibration. First, a signal 1/2 LSB above negative full scale (−4.9988 V for the ±5 V range) is applied and R1 is trimmed to give the first transition (0000 0000 0000 to 0000 0000 0001). Then a signal 1 1/2 LSB below positive full scale (+4.9963 V for the ±5 V range) is applied and R2 trimmed to give the last transition (1111 1111 1110 to 1111 1111 1111).

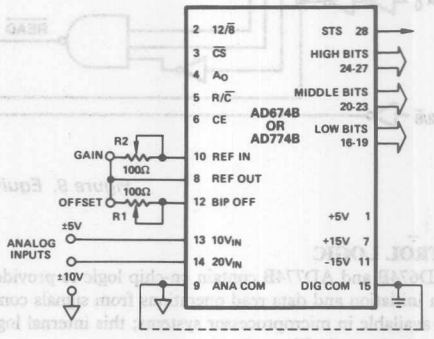

Figure 8. Bipolar Input Connections

GROUNDING CONSIDERATIONS

The analog common at Pin 9 is the ground reference point for the internal reference and is thus the "high quality" ground for the ADC; it should be connected directly to the analog reference point of the system. In order to achieve the high accuracy performance available from the ADC in an environment of high digital noise content, it is required that the analog and digital commons be connected together at the package. In some situations, the digital common at Pin 15 can be connected to the most convenient ground reference point; digital power return is preferred.

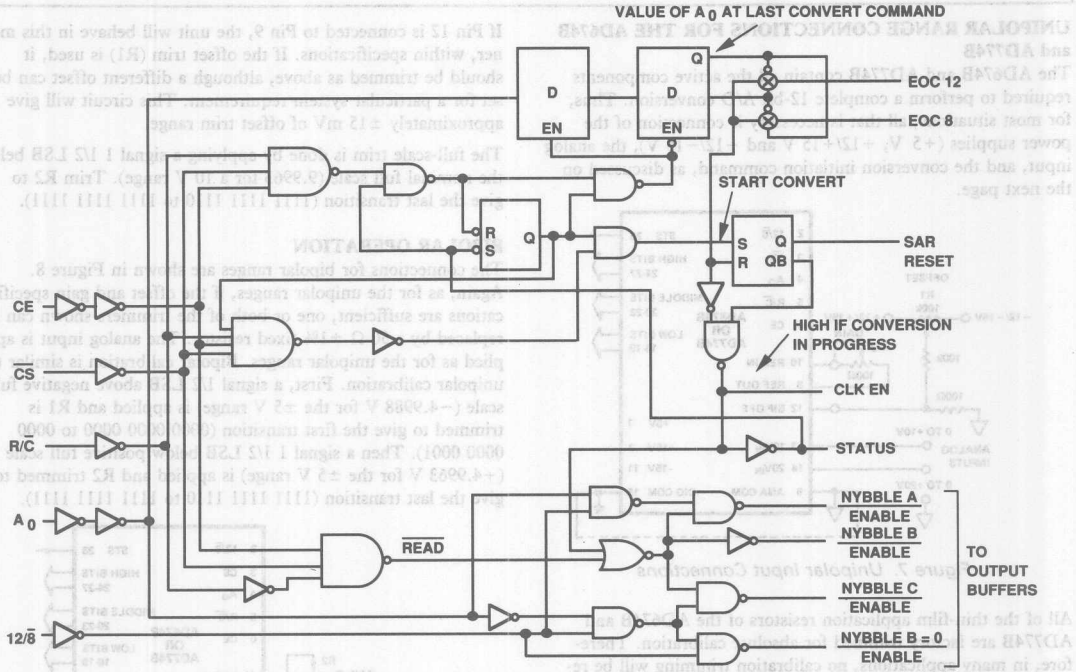

Figure 9. Equivalent Internal Logic Circuitry

CONTROL LOGIC

The AD674B and AD774B contain on-chip logic to provide conversion initiation and data read operations from signals commonly available in microprocessor systems; this internal logic circuitry is shown in Figure 9.

The control signals CE, $\overline{CS}$, and R/$\overline{C}$ control the operation of the converter. The state of R/$\overline{C}$ when CE and $\overline{CS}$ are both asserted determines whether a data read (R/$\overline{C}$ = 1) or a convert (R/$\overline{C}$ = 0) is in progress. The register control inputs A_0 and 12/$\overline{8}$ control conversion length and data format. If a conversion is started with A_0 low, a full 12-bit conversion cycle is initiated. If A_0 is high during a convert start, a shorter 8-bit conversion cycle results. During data read operations, A_0 determines whether the three-state buffers containing the 8 MSBs of the conversion result (A_0 = 0) or the 4 LSBs (A_0 = 1) are enabled. The 12/$\overline{8}$ pin determines whether the output data is to be organized as two 8-bit words (12/$\overline{8}$ tied to DIGITAL COMMON) or a single 12-bit word (12/$\overline{8}$ tied to V_{LOGIC}). In the 8-bit mode, the byte addressed when A_0 is high contains the 4 LSBs from the conversion followed by four trailing zeroes. This organization allows the data lines to be overlapped for direct interface to 8-bit buses without the need for external three-state buffers.

An output signal, STS, indicates the status of the converter. STS goes high at the beginning of a conversion and returns low when the conversion cycle is complete.

Table I. Truth Table

CE	$\overline{CS}$	R/$\overline{C}$	12/$\overline{8}$	A_0	Operation
0	X	X	X	X	None
X	1	X	X	X	None
1	0	0	X	0	Initiate 12-Bit Conversion
1	0	0	X	1	Initiate 8-Bit Conversion
1	0	1	1	X	Enable 12-Bit Parallel Output
1	0	1	0	0	Enable 8 Most Significant Bits
1	0	1	0	1	Enable 4 LSBs +4 Trailing Zeroes

The ADC may be operated in one of two modes, the full-control mode and the stand-alone mode. The full-control mode utilizes all the control signals and is useful in systems that address decode multiple devices on a single data bus. The stand-alone mode is useful in systems with dedicated input ports available. In general, the stand-alone mode is capable of issuing start-convert commands on a more precise basis and, therefore, produces higher accuracy results. The following sections describe these two modes in more detail.

FULL-CONTROL MODE

Chip Enable (CE), Chip Select ($\overline{CS}$) and Read/Convert (R/$\overline{C}$) are used to control Convert or Read modes of operation. Either CE or $\overline{CS}$ may be used to initiate a conversion. The state of R/$\overline{C}$ when CE and $\overline{CS}$ are both asserted determines whether a data Read (R/$\overline{C}$ = 1) or a Convert (R/$\overline{C}$ = 0) is in progress. R/$\overline{C}$ should be LOW before both CE and $\overline{CS}$ are asserted; if R/$\overline{C}$ is HIGH, a Read operation will momentarily occur, possibly resulting in system bus contention.

STAND-ALONE MODE

"Stand-alone" mode is useful in systems with dedicated input ports available and thus not requiring full bus interface capability. Stand-alone mode applications are generally able to issue conversion start commands more precisely than full-control mode, resulting in improved accuracy.

CE and 12/$\overline{8}$ are wired HIGH, $\overline{CS}$ and A_0 are wired LOW, and conversion is controlled by R/$\overline{C}$. The three-state buffers are enabled when R/$\overline{C}$ is HIGH and a conversion starts when R/$\overline{C}$ goes LOW. This gives rise to two possible control signals—a high pulse or a low pulse. Operation with a low pulse is shown in Figure 4a. In this case, the outputs are forced into the high impedance state in response to the falling edge of R/$\overline{C}$ and return to valid logic levels after the conversion cycle is completed. The STS line goes HIGH 200 ns after R/$\overline{C}$ goes LOW and returns low 600 ns after data is valid.

If conversion is initiated by a high pulse as shown in Figure 4b, the data lines are enabled during the time when R/$\overline{C}$ is HIGH. The falling edge of R/$\overline{C}$ starts the next conversion, and the data lines return to three-state (and remain three-state) until the next high pulse of R/$\overline{C}$.

CONVERSION TIMING

Once a conversion is started, the STS line goes HIGH. Convert start commands will be ignored until the conversion cycle is complete. The output data buffers can be enabled up to 1.2 µs prior to STS going LOW. The STS line will return LOW at the end of the conversion cycle.

The register control inputs, A_0 and 12/$\overline{8}$, control conversion length and data format. If a conversion is started with A_0 LOW, a full 12-bit conversion cycle is initiated. If A_0 is HIGH during a convert start, a shorter 8-bit conversion cycle results.

During data read operations, A_0 determines whether the three-state buffers containing the 8 MSBs of the conversion result (A_0 = 0) or the 4 LSBs (A_0 = 1) are enabled. The 12/$\overline{8}$ pin determines whether the output data is to be organized as two 8-bit words (12/$\overline{8}$ tied LOW) or a single 12-bit word (12/$\overline{8}$ tied HIGH). In the 8-bit mode, the byte addressed when A_0 is high contains the 4 LSBs from the conversion followed by four trailing zeroes. This organization allows the data lines to be overlapped for direct interface to 8-bit buses without the need for external three-state buffers.

GENERAL A/D CONVERTER INTERFACE CONSIDERATIONS

A typical A/D converter interface routine involves several operations. First, a write to the ADC address initiates a conversion. The processor must then wait for the conversion cycle to complete, since most integrated circuit ADCs take longer than one instruction cycle to complete a conversion. Valid data can, of course, only be read after the conversion is complete. The AD674B and AD774B provide an output signal (STS) which indicates when a conversion is in progress. This signal can be polled by the processor by reading it through an external three-state buffer (or other input port). The STS signal can also be used to generate an interrupt upon completion of conversion if the system timing requirements are critical and the processor has other tasks to perform during the ADC conversion cycle. Another possible time-out method is to assume that the ADC will take its maximum conversion time to convert, and insert a sufficient number of "no-op" instructions to ensure that this amount of processor time is consumed.

Once conversion is complete, the data can be read. For converters with more data bits than are available on the bus, a choice of data formats is required, and multiple read operations are needed. The AD674B and AD774B include internal logic to permit direct interface to 8-bit and 16-bit data buses, selected by the 12/$\overline{8}$ input. In 16-bit bus applications (12/$\overline{8}$ high) the data lines (DB11 through DB0) may be connected to either the 12 most significant or 12 least significant bits of the data bus. The remaining four bits should be masked in software. The interface to an 8-bit data bus (12/$\overline{8}$ low) is done in a left-justified format. The even address (A0 low) contains the 8 MSBs (DB11 through DB4). The odd address (A0 high) contains the 4 LSBs (DB3 through DB0) in the upper half of the byte, followed by four trailing zeroes, thus eliminating bit masking instructions.

It is not possible to rearrange the output data lines for right-justified 8-bit bus interface.

	D7							D0
XXX0 (EVEN ADDR)	DB11 (MSB)	DB10	DB9	DB8	DB7	DB6	DB5	DB4
XXX1 (ODD ADDR)	DB3	DB2	DB1	DB0 (LSB)	0	0	0	0

Figure 10. Data Format for 8-Bit Bus

FULL-CONTROL MODE

Chip Enable ($\overline{CE}$), Chip Select ($\overline{CS}$) and Read/$\overline{Convert}$ ($R/\overline{C}$) are used to control Convert or Read modes of operation. Either $\overline{CE}$ or $\overline{CS}$ may be used to initiate a conversion. The state of $R/\overline{C}$ when $\overline{CE}$ and $\overline{CS}$ are both asserted determines whether a data Read ($R/\overline{C}$ = 1) or a Convert ($R/\overline{C}$ = 0) is in progress. $R/\overline{C}$ should be LOW before both $\overline{CE}$ and $\overline{CS}$ are asserted; if $R/\overline{C}$ is HIGH, a Read operation will momentarily occur, possibly re-sulting in system bus contention.

STAND-ALONE MODE

"Stand-alone" mode is useful in systems with dedicated input ports available and thus not requiring full bus interface capabil-ity. Stand-alone mode applications are generally able to issue conversion start commands more precisely than full-control mode, resulting in improved accuracy.

$\overline{CE}$ and 12/$\overline{8}$ are wired HIGH, $\overline{CS}$ and A_0 are wired LOW, and conversion is controlled by $R/\overline{C}$. The three-state buffers are en-abled when $R/\overline{C}$ is HIGH and a conversion starts when $R/\overline{C}$ goes LOW. This gives rise to two possible control signals—a high pulse or a low pulse. Operation with a low pulse is shown in Figure 4a. In this case, the outputs are forced into the high im-pedance state in response to the falling edge of $R/\overline{C}$ and return to valid logic levels after the conversion cycle is completed. The STS line goes HIGH 200 ns after $R/\overline{C}$ goes LOW and returns low 600 ns after data is valid.

If conversion is initiated by a high pulse as shown in Figure 4b, the data lines are enabled during the time when $R/\overline{C}$ is HIGH. The falling edge of $R/\overline{C}$ starts the next conversion, and the data lines return to three-state (and remain three-state) until the next high pulse of $R/\overline{C}$.

CONVERSION TIMING

Once a conversion is started, the STS line goes HIGH. Convert start commands will be ignored until the conversion cycle is complete. The output data buffers can be enabled up to 1.2 µs prior to STS going LOW. The STS line will return LOW at the end of the conversion cycle.

The register control inputs, A_0 and 12/$\overline{8}$, control conversion length and data format. If a conversion is started with A_0 LOW, a full 12-bit conversion cycle is initiated. If A_0 is HIGH during a convert start, a shorter 8-bit conversion cycle results.

During data read operations, A_0 determines whether the three-state buffers containing the 8 MSBs of the conversion result (A_0 = 0) or the 4 LSBs (A_0 = 1) are enabled. The 12/$\overline{8}$ pin de-termines whether the output data is to be organized as two 8-bit words (12/$\overline{8}$ tied LOW) or a single 12-bit word (12/$\overline{8}$ tied HIGH). In the 8-bit mode, the byte addressed when A_0 is high contains the 4 LSBs from the conversion followed by four trail-ing zeros. This organization allows the data lines to be over-lapped for direct interface to 8-bit buses without the need for external three-state buffers.

GENERAL A/D CONVERTER INTERFACE CONSIDERATIONS

A typical A/D converter interface routine involves several opera-tions. First, a write to the ADC address initiates a conversion. The processor must then wait for the conversion cycle to com-plete, since most integrated circuit ADCs take longer than one instruction cycle to complete a conversion. Valid data can, of course, only be read after the conversion is complete. The ADC674B and ADJ774B provide an output signal (STS) which indicates when a conversion is in progress. This signal can be polled by the processor by reading it through an external three-state buffer (or other input port). The STS signal can also be used to generate an interrupt upon completion of conversion if the system timing requirements are critical and the processor has other tasks to perform during the ADC conversion cycle. Another possible time-out method is to assume that the ADC will take its maximum conversion time to convert, and insert a sufficient number of "no-op" instructions to ensure that this amount of processor time is consumed.

Once conversion is complete, the data can be read. For conver-ters with more data bits than are available on the bus, a choice of data formats is required, and multiple read operations are needed. The ADC674B and ADJ774B include internal logic to per-mit direct interface to 8-bit and 16-bit data buses, selected by the 12/$\overline{8}$ input. In 16-bit bus applications (12/$\overline{8}$ high) the data lines (DB11 through DB0) may be connected to either the 12 most significant or 12 least significant bits of the data bus. The remaining four bits should be masked in software. The interface to an 8-bit data bus (12/$\overline{8}$ low) is done in a left-justified format. The even address (A0 low) contains the 8 MSBs (DB11 through DB4). The odd address (A0 high) contains the 4 LSBs (DB3 through DB0) in the upper half of the byte, followed by four trailing zeros, thus eliminating bit masking instructions.

It is not possible to rearrange the output data lines for right-justified 8-bit bus interface.

24-Pin "Skinny" DIP Package

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD675 is a multipurpose 16-bit parallel output analog-to-digital converter which utilizes a switched capacitor/charge redistribution architecture to achieve a 100 kSPS conversion rate (10 µs total conversion time). Overall performance is optimized by digitally correcting internal nonlinearities through on-chip autocalibration.

The AD675 includes a sample-hold amplifier (SHA) and microprocessor compatible bus interface with three-state output buffers and two-byte read. Output data is also available in serial format.

The AD675 circuitry is segmented onto two monolithic chips—a digital control chip fabricated on Analog Devices' DSP CMOS process and an analog ADC chip fabricated on our BiMOS II process. Both chips are contained in a single package.

The AD675 is specified for ac (or "dynamic") parameters such as S/N+D Ratio, THD and IMD which are important in signal processing applications. In addition, dc parameters are specified which are important in measurement applications.

PRELIMINARY TECHNICAL DATA

The AD675 operates from +5 V and ±12 V supplies and typically consumes 235 mW during conversion. The digital supply (V_{DD}) is separated from the analog supplies (V_{CC}, V_{EE}) for reduced digital crosstalk. An analog ground sense is provided for the analog input. Separate analog and digital grounds are also provided.

The AD675 is available in a 24-pin plastic "skinny" DIP or 24-pin side-brazed "skinny" DIP ceramic package. Screening to MIL-STD-883C Class B is available.

PRODUCT DESCRIPTION

The AD676 is a multipurpose 16-bit parallel output analog-to-digital converter which utilizes a switched-capacitor/charge redistribution architecture to achieve a 100 kSPS conversion rate (10 μs total conversion time). Overall performance is optimized by digitally correcting internal nonlinearities through on-chip autocalibration.

The AD676 circuitry is segmented onto two monolithic chips—a digital control chip fabricated on Analog Devices DSP CMOS process and an analog ADC chip fabricated on our BiMOS II process. Both chips are contained in a single package.

The AD676 is specified for ac (or "dynamic") parameters such as S/(N+D) Ratio, THD and IMD which are important in signal processing applications. In addition, dc parameters are specified which are important in measurement applications.

The AD676 operates from +5 V and ±12 V supplies and typically consumes 235 mW during conversion. The digital supply (V_{DD}) is separated from the analog supplies (V_{CC}, V_{EE}) for reduced digital crosstalk. An analog ground sense is provided for the analog input. Separate analog and digital grounds are also provided.

The AD676 is available in a 28-pin plastic DIP or 28-pin side-brazed ceramic package.

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

AD676—SPECIFICATIONS

AC SPECIFICATIONS (T_{MIN} to T_{MAX}, V_{CC} = +12 V ± 5%, V_{EE} = −12 V ± 5%, V_{DD} = +5 V ± 10%)[1]

Parameter	AD676J/A/T Min	AD676J/A/T Typ	AD676J/A/T Max	AD676K/B Min	AD676K/B Typ	AD676K/B Max	Units
Total Harmonic Distortion (THD)							
−0.05 dB Input		−95	−88		−98	−90	dB
		0.002	0.004		0.0015	0.003	%
−20 dB Input		−78			−80		dB
		0.01			0.01		%
−60 dB Input		−40			−45		dB
		1.0			0.05		%
Signal-to-Noise and Distortion Ratio (S/(N+D))							
−0.05 dB Input	85	88		87	90		dB
−20 dB Input		67			70		dB
−60 dB Input		32			34		dB
Peak Spurious or Peak Harmonic Component		−99	−89		−100	−92	dB
Intermodulation Distortion (IMD)[2]							
2nd Order Products		−102			−102		dB
3rd Order Products		−98			−98		dB
Full Power Bandwidth		1			1		MHz

DIGITAL SPECIFICATIONS (for all grades T_{MIN} to T_{MAX}, V_{CC} = +12 V ± 5%, V_{EE} = −12 V ± 5%, V_{DD} = +5 V ± 10%)

Parameter		Test Conditions	Min	Typ	Max	Units
LOGIC INPUTS						
V_{IH}	High-Level Input Voltage		2.4			V
V_{IL}	Low-Level Input Voltage		−0.3		0.8	V
I_{IH}	High-Level Input Current	$V_{IH} = V_{DD}$	−10		+10	μA
I_{IL}	Low-Level Input Current	$V_{IL} = 0$ V	−10		+10	μA
C_{IN}	Input Capacitance			10		pF

ORDERING GUIDE

Model	Temperature Range	S/(N+D)	INL	Package Description	Package Option*
AD676JN	0°C to +70°C	85 dB	±2 LSB	Plastic 28-Pin DIP	N-28
AD676KN	0°C to +70°C	87 dB	±1 LSB	Plastic 28-Pin DIP	N-28
AD676AD	−40°C to +85°C	85 dB	±2 LSB	Ceramic 28-Pin DIP	D-28
AD676BD	−40°C to +85°C	87 dB	±1 LSB	Ceramic 28-Pin DIP	D-28
AD676TD	−55°C to +125°C	85 dB	±2 LSB	Ceramic 28-Pin DIP	D-28

*D = Ceramic DIP; N = Plastic DIP. For outline information see Package Information section.

ABSOLUTE MAXIMUM RATINGS*

V_{DD} to DGND . . . . . 0 to +5.5 V
V_{CC} to AGND . . . . . 0 to +12.6 V
V_{EE} to AGND . . . . . 0 to −12.6 V
AGND to DGND . . . . . ±0.3 V
Digital Inputs to DGND . . . . . 0 to +5.5 V
Analog Inputs to AGND . . . . . $\pm V_{REF}$
Soldering . . . . . +300°C, 10 sec
Storage Temperature . . . . . −60°C to +100°C

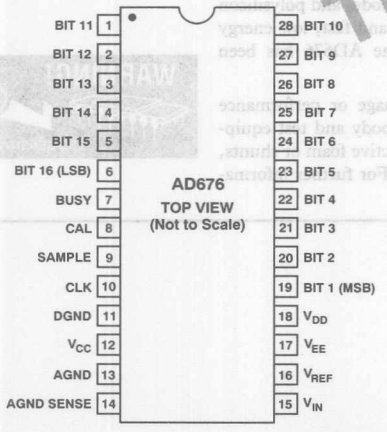
*Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

PRELIMINARY TECHNICAL DATA

CAUTION

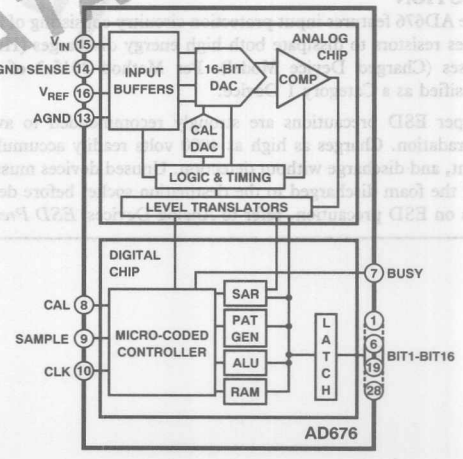
The AD676 features input protection circuitry consisting of large "distributed" diodes and polysilicon series resistors to dissipate both high energy discharges (Human Body Model) and fast, low energy pulses (Charged Device Model). Per Method 3015.2 of MIL-STD-883C, the AD676 has been classified as a Category 1 Device.

Proper ESD precautions are strongly recommended to avoid functional damage or performance degradation. Charges as high as 4000 volts readily accumulate on the human body and test equipment, and discharge without detection. Unused devices must be stored in conductive foam or shunts, and the foam discharged to the destination socket before devices are removed. For further information on ESD precaution, refer to Analog Devices' *ESD Prevention Manual*.



This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

PIN DESCRIPTION



Pin	Name	Type	Description
1–6	BIT11–BIT16	DO	BIT11–BIT16 represent the six LSBs of data.
7	BUSY	DO	Status Line for Converter. Active HIGH, indicating a conversion or calibration in progress. BUSY should be buffered when capacitively loaded.
8	CAL	DI	Calibration Control Pin (Asynchronous).
9	SAMPLE	DI	V_{IN} Acquisition Control Pin. Active HIGH. During conversion, SAMPLE controls the state of the internal sample-hold amplifier and the falling edge initiates conversion (see "Conversion Control" paragraph). During calibration, SAMPLE should be held LOW. If HIGH during calibration, diagnostic information will appear on the two LSBs (Pins 5 and 6).
10	CLK	DI	Master Clock Input. The AD676 requires 17 clock cycles to execute a conversion.
11	DGND	P	Digital Ground.
12	V_{CC}	P	+12 V Analog Supply Voltage.
13	AGND	P/AI	Analog Ground.
14	AGND SENSE	AI	Analog Ground Sense.
15	V_{IN}	AI	Analog Input Voltage.
16	V_{REF}	AI	External Voltage Reference Input.
17	V_{EE}	P	−12 V Analog Supply Voltage.
18	V_{DD}	P	+5 V Logic Supply Voltage.
19–28	BIT1–BIT10	DO	BIT1–BIT10 represent the ten MSB of data.

Type: AI = Analog Input
DI = Digital Input
DO = Digital Output
P = Power

Package Pinout

Functional Block Diagram

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

NYQUIST FREQUENCY
An implication of the Nyquist sampling theorem, the "Nyquist frequency" of a converter is that input frequency which is one half the sampling frequency of the converter.

TOTAL HARMONIC DISTORTION
Total harmonic distortion (THD) is the ratio of the rms sum of the harmonic components to the rms value of a full-scale input signal and is expressed in percent (%) or decibels (dB). For input signals or harmonics that are above the Nyquist frequency, the aliased components are used.

SIGNAL-TO-NOISE PLUS DISTORTION RATIO
Signal-to-noise plus distortion is defined to be the ratio of the rms value of the measured input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc.

GAIN ERROR
The last transition should occur at an analog value 1.5 LSB below the nominal full scale (4.99977 volts for a ±5 V range). The gain error is the deviation of the actual difference between the first and last code transition from the ideal difference between the first and last code transition.

BIPOLAR ZERO ERROR
Bipolar zero error is the difference between the ideal midscale input voltage (0 V) and the actual voltage producing the midscale output code.

DIFFERENTIAL NONLINEARITY (DNL)
In an ideal ADC, code transitions are one LSB apart. Differential nonlinearity is the maximum deviation from this ideal value. It is often specified in terms of resolution for which no missing codes are guaranteed.

INTEGRAL NONLINEARITY (INL)
The ideal transfer function for an ADC is a straight line drawn between "zero" and "full scale." The point used as "zero" occurs 1/2 LSB before the most negative code transition. "Full scale" is defined as a level 1.5 LSB beyond the most positive code transition. Integral nonlinearity is the worst-case deviation of a code from the straight line. The deviation of each code is measured from the middle of that code.

BANDWIDTH
The full-power bandwidth is that input frequency at which the amplitude of the reconstructed fundamental is reduced by 3 dB for a full-scale input.

INTERMODULATION DISTORTION (IMD)
With inputs consisting of sine waves at two frequencies, fa and fb, any device with nonlinearities will create distortion products, of order (m+n), at sum and difference frequencies of mfa ± nfb, where m, n = 0, 1, 2, 3 . . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are (fa + fb) and (fa − fb), and the third order terms are (2 fa + fb), (2 fa − fb), (fa + 2 fb) and (fa − 2 fb). The IMD products are expressed as the decibel ratio of the rms sum of the measured input signals to the rms sum of the distortion terms. The two signals applied to the converter are of equal amplitude, and the peak value of their sum is −0.5 dB from full scale. The IMD products are normalized to a 0 dB input signal.

APERTURE DELAY
Aperture delay is the time required after SAMPLE pin is taken LOW for the internal sample-hold of the AD676 to open, thus holding the value of V_{IN}.

APERTURE JITTER
Aperture jitter is the variation in the aperture delay from sample to sample.

POWER SUPPLY REJECTION
DC variations in the power supply voltage will affect the full-scale transition point, resulting in gain error. Power supply rejection is the maximum change in the full-scale transition point due to a change in power-supply voltage from the nominal value. Additionally, there is another power supply variation to consider. AC ripple on the power supplies can couple noise into the ADC, resulting in degradation of dynamic performance. This is displayed in Figure 15.

INPUT SETTLING TIME
Settling time is a function of the SHA'a ability to track fast slewing signals. This is specified as the maximum time required in track mode after a full-scale step input to guarantee rated conversion accuracy.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

FUNCTIONAL DESCRIPTION

The AD676 is a multipurpose 16-bit analog-to-digital converter and includes circuitry which performs an input sample/hold function, ground sense, and autocalibration. These functions are segmented onto two monolithic chips—an analog signal processor and a digital controller. Both chips are contained within the AD676 package.

The AD676 employs a successive-approximation technique to determine the value of the analog input voltage. However, instead of the traditional laser-trimmed resistor-ladder approach, this device uses a capacitor-array, charge redistribution technique. Binary-weighted capacitors subdivide the input sample to perform the actual analog-to-digital conversion. The capacitor array eliminates variation in the linearity of the device due to temperature-induced mismatches of resistor values. Since a capacitor array is used to perform the data conversions, the sample/hold function is included without the need for additional external circuitry.

Initial errors in capacitor matching are eliminated by an autocalibration circuit within the AD676. This circuit employs an on-chip microcontroller and a calibration DAC to measure and compensate capacitor mismatch errors. As each error is determined, its value is stored in on-chip memory (RAM). Subsequent conversions use these RAM values to improve conversion accuracy. The autocalibration routine may be invoked at any time. Autocalibration insures high performance while eliminating the need for any user adjustments and is described in detail below.

The microcontroller controls all of the various functions within the AD676. These include the actual successive approximation algorithm, the autocalibration routine, the sample/hold operation, and the internal output data latch.

AUTOCALIBRATION

The AD676 achieves rated performance without the need for user trims or adjustments. This is accomplished through the use of on-chip autocalibration.

In the autocalibration sequence, sample/hold offset is nulled by internally connecting the input circuit to the ground sense circuit. The resulting offset voltage is measured and stored in RAM for later use. Next, the capacitor representing the most significant bit (MSB) is charged to the reference voltage. This charge is then transferred to a capacitor of equal size (composed of the sum of the remaining lower weight bits). The difference in the voltage that results and the reference voltage represents the amount of capacitor mismatch. A calibration digital-to-analog converter (DAC) adds an appropriate value of error correction voltage to cancel this mismatch. This correction factor is also stored in RAM. This process is repeated for each of the capacitors representing the remaining top eight bits. The accumulated values in RAM are then used during subsequent conversions to adjust conversion results accordingly.

As shown in Figure 1, when CAL is taken HIGH the AD676 internal circuitry is reset, the BUSY pin is driven HIGH, and the ADC prepares for calibration. This is an asynchronous hardware reset and will interrupt any conversion or calibration currently in progress. Actual calibration begins when CAL is taken LOW and completes in 85,530 clock cycles, indicated by BUSY going LOW. During calibration, it is preferable for SAMPLE to be held LOW. If SAMPLE is HIGH, diagnostic data will appear on Pins 5 and 6. This data is of no value to the user.

The AD676 requires one clock cycle after BUSY goes LOW to complete the calibration cycle. If this clock cycle is not provided, it will be taken from the first conversion, likely resulting in first conversion error.

In most applications, it is sufficient to calibrate the AD676 only upon power-up, in which case care should be taken that the power supplies and voltage reference have stabilized first.

CONVERSION CONTROL

The AD676 is controlled by two signals: SAMPLE and CLK, as shown in Figures 2a and 2b. It is assumed that the part has been calibrated and the digital I/O pins have the levels shown at the start of the timing diagram.

A conversion consists of an input acquisition followed by 17 clock pulses which execute the 16-bit internal successive approximation routine. The analog input is acquired by taking the SAMPLE line HIGH for a minimum sampling time of t_S. The actual sample taken is the voltage present on V_{IN} one aperture delay after the SAMPLE line is brought LOW, assuming the previous conversion has completed (signified by BUSY going LOW). Care should be taken to ensure that this negative edge is well defined and jitter free in ac applications to reduce the uncertainty (noise) in signal acquisition. With SAMPLE going LOW, the AD676 commits itself to the conversion—the input at V_{IN} is disconnected from the internal capacitor array, BUSY goes HIGH, and the SAMPLE input will be ignored until the conversion is completed (when BUSY goes LOW). SAMPLE must be held LOW for a minimum period of time t_{SL}. A period of time t_{SC} after bringing SAMPLE LOW, the 17 CLK cycles are applied; CLK pulses that start before this period of time are ignored. BUSY goes HIGH t_{SB} after SAMPLE goes LOW, signifying that a conversion is in process, and remains HIGH until the conversion is completed. BUSY goes LOW during the 17th CLK cycle at the point where the data outputs have changed and are valid. The AD676 will ignore CLK after BUSY has gone LOW and the output data will remain constant until a new conversion is completed. The data can, therefore, be read any time after BUSY goes LOW and before the 17th CLK of the next conversion (see Figures 2a and 2b). The section on Microprocessor Interfacing discusses how the AD676 can be interfaced to a 16-bit databus.

Typically BUSY would be used to latch the AD676 output data into buffers or to interrupt microprocessors or DSPs. It is recommended that the capacitive load on BUSY be minimized by driving no more than a single logic input. Higher capacitive loads such as cables or multiple gates may degrade conversion quality unless BUSY is buffered.

CONTINUOUS CONVERSION

For maximum throughput rate, the AD676 can be operated in a continuous convert mode (see Figure 2b). This is accomplished

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

by utilizing the fact that SAMPLE will no longer be ignored after BUSY goes LOW, so an acquisition may be initiated even during the HIGH time of the 17th CLK pulse for maximum throughput rate while enabling full settling of the sample/hold circuitry. If SAMPLE is already HIGH when BUSY goes LOW at the end of a conversion, then an acquisition is immediately initiated and t_S and t_C start from that time. Data from the previous conversion may be latched up to t_{SD} before BUSY goes LOW or t_{OD} after the rising edge of the 17th clock pulse. However, it is preferred that latching occur on or after the falling edge of BUSY.

Care must be taken to adhere to the minimum/maximum timing requirements in order to preserve conversion accuracy.

GENERAL CONVERSION GUIDELINES

During signal acquisition and conversion, care should be taken with the logic inputs to avoid digital feedthrough noise. It is possible to run CLK continuously, even during the sample period. However, CLK edges during the sampling period, and especially when SAMPLE goes LOW, may inject noise into the sampling process. The AD676 is tested with no CLK cycles during the sampling period. The BUSY signal can be used to prevent the clock from running during acquisition, as illustrated in Figure 3. In this circuit BUSY is used to reset the circuitry which divides the system clock down to provide the AD676 CLK. This serves to interrupt the clock until after the input signal has been acquired, which has occurred when BUSY goes HIGH. When the conversion is completed and BUSY goes LOW, the circuit in Figure 3 truncates the 17th CLK pulse width which is tolerable because only its rising edge is critical.

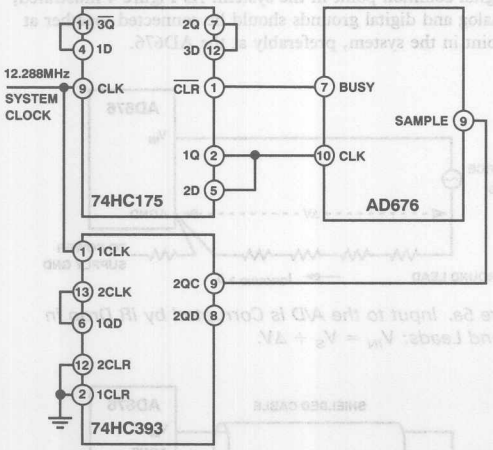

Figure 3.

Figure 3 also illustrates the use of a counter (74HC393) to derive the AD676 SAMPLE command from the system clock when a continuous convert mode is desirable. Pin 9 (2QC) provides a 96 kHz sample rate for the AD676 when used with a 12.288 MHz system clock. Alternately, Pin 8 (2QD) could be used for a 48 kHz rate.

If a continuous clock is used, then the user must avoid CLK edges at the instant of disconnecting V_{IN} which occurs at the falling edge of SAMPLE (see t_{SC} specification). The duty cycleof CLK may vary, but both the HIGH (t_{CH}) and LOW (t_{CL}) phases must conform to those shown in the timing specifications. The internal comparator makes its decisions on the rising edge of CLK. To avoid a negative edge transition disturbing the comparator's settling, t_{CL} should be at least half the value of t_{CLK}. To also avoid transitions disturbing the internal comparator's settling, it is not recommended that the SAMPLE pin change state toward the end of a CLK cycle.

During a conversion, internal dc error terms such as comparator voltage offset are sampled, stored on internal capacitors and used to correct for their corresponding errors when needed. Because these voltages are stored on capacitors, they are subject to leakage decay and so require refreshing. For this reason there is a maximum conversion time t_C.

Output coding for the AD676 is twos complement, as shown in the following table. By inverting the MSB, the coding can be converted to offset binary.

Table 1. Output Coding

V_{IN}	Output Code
Full Scale	011 . . . 11
Full Scale − 1 LSB	011 . . . 10
Midscale + 1 LSB	000 . . . 01
Midscale	000 . . . 00
Midscale − 1 LSB	111 . . . 11
−Full Scale + 1 LSB	100 . . . 01
−Full Scale	100 . . . 00

POWER SUPPLIES AND DECOUPLING

The AD676 has three power supply input pins. V_{CC} and V_{EE} provide the supply voltages to operate the analog portions of the AD676 including the ADC and sample-hold amplifier (SHA). V_{DD} provides the supply voltage which operates the digital portions of the AD676 including the data output buffers and the autocalibration controller.

As with most high performance linear circuits, changes in the power supplies can produce undesired changes in the performance of the circuit. Optimally, well regulated power supplies with less than 1% ripple should be selected. The ac output impedance of a power supply is a complex function of frequency, and in general will increase with frequency. In other words, high frequency switching such as that encountered with digital circuitry requires fast transient currents which most power supplies cannot adequately provide. This results in voltage spikes on the supplies. If these spikes exceed the ±5% tolerance of the ±12 V supplies or the ±10% limits of the +5 V supply, ADC performance will degrade. Additionally, spikes at frequencies higher than 100 kHz will also degrade performance. To compensate for the finite ac output impedance of the supplies, it is necessary to store "reserves" of charge in bypass capacitors. These capacitors can effectively lower the ac impedance presented to the AD676 power inputs which in turn will significantly reduce the magnitude of the voltage spikes. For bypassing to be effective, certain guidelines should be followed. Decoupling capacitors, typically 0.1 μF, should be placed as closely as possible to each power supply pin of the AD676. It is essential that these

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

capacitors be placed physically close to the IC to minimize the inductance of the PCB trace between the capacitor and the supply pin. The logic supply (V_{DD}) should be decoupled to digital common and the analog supplies (V_{CC} and V_{EE}) to analog common. The reference input is also considered as a power supply pin in this regard and the same decoupling procedures apply. These points are displayed in Figure 4.

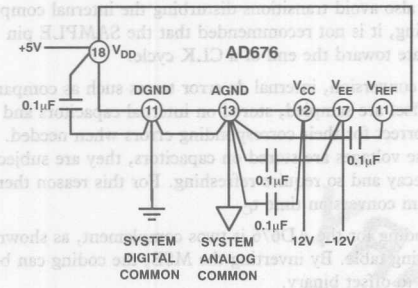

Figure 4. Grounding and Decoupling the AD676

Additionally, it is beneficial to have large capacitors (>47 μF) located at the point where the power connects to the PCB with 10 μF capacitors located in the vicinity of the ADC to further reduce low frequency ripple. In systems that will be subjected to particularly harsh environmental noise, additional decoupling may be necessary. RC-filtering on each power supply combined with dedicated voltage regulation can substantially decrease power supply ripple effects (this is further detailed in Figure 7).

BOARD LAYOUT

Designing with high resolution data converters requires careful attention to board layout. Trace impedance is a significant issue. A 1.22 mA current through a 0.5 Ω trace will develop a voltage drop of 0.6 mV, which is 4 LSBs at the 16-bit level for a 10 V full-scale span. In addition to ground drops, inductive and capacitive coupling need to be considered, especially when high accuracy analog signals share the same board with digital signals.

Analog and digital signals should not share a common return path. Each signal should have an appropriate analog or digital return routed close to it. Using this approach, signal loops enclose a small area, minimizing the inductive coupling of noise. Wide PC tracks, large gauge wire, and ground planes are highly recommended to provide low impedance signal paths. Separate analog and digital ground planes are also desirable, with a single interconnection point at the AD676 to minimize interference between analog and digital circuitry. Analog signals should be routed as far as possible from digital signals and should cross them, if at all, only at right angles. A solid analog ground plane around the AD676 will isolate it from large switching ground currents. For these reasons, the use of wire wrap circuit construction will not provide adequate performance; careful printed circuit board construction is preferred.

GROUNDING

The AD676 has three grounding pins, designated ANALOG GROUND (AGND), DIGITAL GROUND (DGND) and ANALOG GROUND SENSE (AGND SENSE). The analog ground pin is the "high quality" ground reference point for the device, and should be connected to the analog common point in the system.

AGND SENSE is intended to be connected to the input signal ground reference point. This allows for slight differences in level between the analog ground point in the system and the input signal ground point. However no more than 100 mV is recommended between the AGND and the AGND SENSE pins for specified performance.

Using AGND SENSE to remotely sense the ground potential of the signal source can be useful if the signal has to be carried some distance to the A/D converter. Since all IC ground currents have to return to the power supply and no ground leads are free from resistance and inductance, there are always some voltage differences from one ground point in a system to another.

Over distance this voltage difference can easily amount to several LSBs (in a 10 V input span, 16-bit system each LSB is about 0.15 mV). This would directly corrupt the A/D input signal if the A/D measures its input with respect to power ground (AGND) as shown in Figure 5a. To solve this problem the AD676 offers an AGND SENSE pin. Figure 5b shows how the AGND SENSE can be used to eliminate the problem in Figure 5a. Figure 5b also shows how the signal wires should be shielded in a noisy environment to avoid capacitive coupling. If inductive (magnetic) coupling is expected to be dominant such as where motors are present, twisted-pair wires should be used instead.

The digital ground pin is the reference point for all of the digital signals that operate the AD676. This pin should be connected to the digital common point in the system. As Figure 4 illustrated, the analog and digital grounds should be connected together at one point in the system, preferably at the AD676.

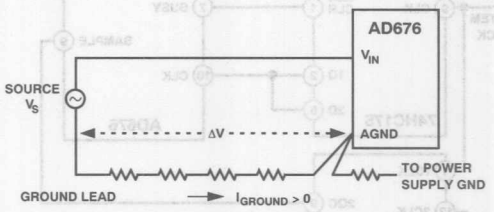

Figure 5a. Input to the A/D Is Corrupted by IR Drop in Ground Leads: $V_{IN} = V_S + \Delta V$.

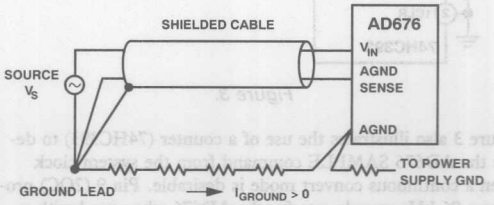

Figure 5b. AGND SENSE Eliminates the Problem in Figure 5a.

VOLTAGE REFERENCE

The AD676 requires the use of an external voltage reference. The input voltage range is determined by the value of the reference voltage; in general, a reference voltage of n volts allows an input range of ±n volts. The AD676 is specified for both 10 V and 5.0 V references. A 10 V reference will typically require support circuitry operated from ±15 V supplies; a 5.0 V reference may be used with ±12 V supplies. Signal-to-noise performance is increased proportionately with input signal range. In the presence of a fixed amount of system noise, increasing the LSB size (which results from increasing the reference voltage) will increase the effective S/(N+D) performance. Figure 12 illustrates S/(N+D) as a function of reference voltage. In contrast, INL will be optimal at lower reference voltage values (such as 5 V) due to capacitor nonlinearity at higher voltage values.

During a conversion, the switched capacitor array of the AD676 presents a dynamically changing current load at the voltage reference as the successive-approximation algorithm cycles through various choices of capacitor weighting. The output impedance of the reference circuitry must be low so that the output voltage will remain sufficiently constant as the current drive changes. In some applications, this may require that the output of the voltage reference be buffered by an amplifier with low impedance at relatively high frequencies. In choosing a voltage reference, consideration should be made for selecting one with low noise. A capacitor connected between REF IN and AGND will reduce the demands on the reference by decreasing the magnitude of high frequency components required to be sourced by the reference.

Figures 6 and 7 represent typical design approaches.

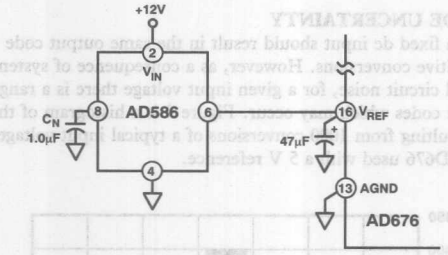

Figure 6.

Figure 6 shows a voltage reference circuit featuring the 5 V output AD586. The AD586 is a low cost reference which utilizes a buried Zener architecture to provide low noise and drift. Over the 0°C to +70°C range, the AD586L grade exhibits less than 2.25 mV output change from its initial value at +25°C. A noise-reduction capacitor, C_N, reduces the broadband noise of the AD586 output, thereby optimizing the overall performance of the AD676. It is recommended that a 10 µF to 47 µF high quality tantalum capacitor be tied between the V_{REF} input of the AD676 and ground to minimize the impedance on the reference.

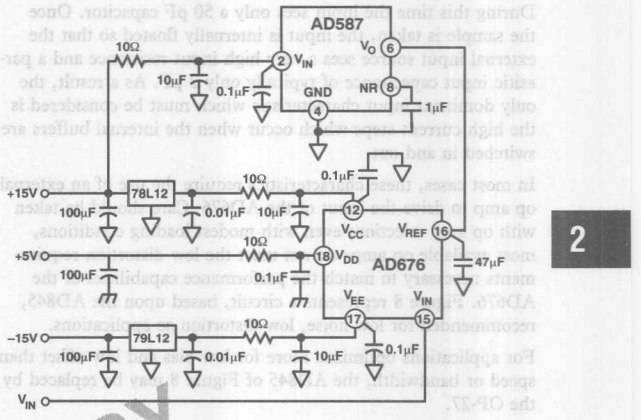

Figure 7.

Using the AD676 with ±10 V input range (V_{REF} = 10 V) typically requires ±15 V supplies to drive op amps and the voltage reference. If ±12 V is not available in the system, regulators such as 78L12 and 79L12 can be used to provide power for the AD676. This is also the recommended approach (for any input range) when the ADC system is subjected to harsh environments such as where the power supplies are noisy and where voltage spikes are present. Figure 7 shows an example of such a system based upon the 10 V AD587 reference, which provides a 300 µV LSB. Circuitry for additional protection against power supply disturbances has been shown. A 100 µF capacitor at each regulator prevents very large voltage spikes from entering the regulators. Any power line noise which the regulators cannot eliminate will be further filtered by an RC filter (10 Ω/10 µF) having a −3 dB point at 1.6 kHz. For best results the regulators should be within a few centimeters of the AD676.

ANALOG INPUT

As previously discussed, the analog input voltage range for the AD676 is ±V_{REF}. For purposes of ground drop and common mode rejection, the V_{IN} and V_{REF} inputs each have their own ground. V_{REF} is referred to the local analog system ground (AGND), and V_{IN} is referred to the analog ground sense pin (AGND SENSE) which allows a remote ground sense for the input signal.

The AD676 analog inputs (V_{IN}, V_{REF} and AGND SENSE) exhibit dynamic characteristics. When a conversion cycle begins, each analog input is connected to an internal, discharged 50 pF capacitor which then charges to the voltage present at the corresponding pin. The capacitor is disconnected when SAMPLE is taken LOW, and the stored charge is used in the subsequent conversion. In order to limit the demands placed on the external source by this high initial charging current, an internal buffer amplifier is employed between the input and this capacitance for a few hundred nanoseconds. During this time the input pin exhibits typically 20 kΩ input resistance, 10 pF input capacitance and ±40 µA bias current. Next, the input is switched directly

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

to the now precharged capacitor and allowed to fully settle. During this time the input sees only a 50 pF capacitor. Once the sample is taken, the input is internally floated so that the external input source sees a very high input resistance and a parasitic input capacitance of typically only 2 pF. As a result, the only dominant input characteristic which must be considered is the high current steps which occur when the internal buffers are switched in and out.

In most cases, these characteristics require the use of an external op amp to drive the input of the AD676. Care should be taken with op amp selection; even with modest loading conditions, most available op amps do not meet the low distortion requirements necessary to match the performance capabilities of the AD676. Figure 8 represents a circuit, based upon the AD845, recommended for low noise, low distortion ac applications.

For applications optimized more for low bias and low offset than speed or bandwidth, the AD845 of Figure 8 may be replaced by the OP-27.

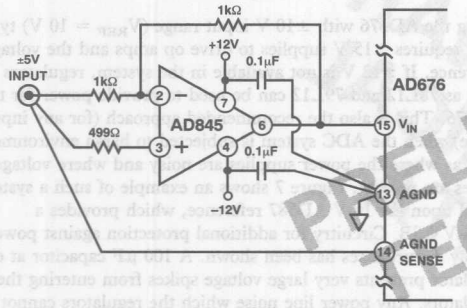

Figure 8.

AC PERFORMANCE

AC parameters, which include S/(N+D), THD, etc., reflect the AD676's effect on the spectral content of the analog input signal. Figures 12 through 16 provide information on the AD676's ac performance under a variety of conditions.

As a general rule, averaging the results from several conversions reduces the effects of noise, and therefore improves such parameters as S/(N+D). AD676 performance may be optimized by operating the device at its maximum sample rate of 100 kSPS and digitally filtering the resulting bit stream to the desired signal bandwidth. This succeeds in distributing noise over a wider frequency range, thus reducing the noise density in the frequency band of interest. This subject is discussed in the following section.

OVERSAMPLING AND NOISE FILTERING

The Nyquist rate for a converter is defined as one-half its sampling rate. This is established by the Nyquist theorem, which requires that a signal be sampled at a rate corresponding to at least twice its highest frequency component of interest in order to preserve the informational content. Oversampling is a conversion technique in which the sampling frequency is more than twice the frequency bandwidth of interest. In audio applications, the AD676 can operate at a 2 × F_S oversampling rate, where F_S = 48 kHz.

In quantized systems, the informational content of the analog input is represented in the frequency spectrum from dc to the Nyquist rate of the converter. Within this same spectrum are higher frequency noise and signal components. Antialias, or low pass, filters are used at the input to the ADC to reduce these noise and signal components so that their aliased components do not corrupt the baseband spectrum. However, wideband noise contributed by the AD676 will not be reduced by the antialias filter. The AD676 quantization noise is evenly distributed from dc to the Nyquist rate, and this fact can be used to minimize its overall affect.

The AD676 quantization noise effects can be reduced by oversampling—sampling at a rate higher than that defined by the Nyquist theorem. This spreads the noise energy over a bandwidth wider than the frequency band of interest. By judicious selection of a digital decimation filter, noise frequencies outside the bandwidth of interest may be eliminated.

The process of analog to digital conversion inherently produces noise, known as quantization noise. The magnitude of this noise is a function of the resolution of the converter, and manifests itself as a limit to the theoretical signal-to-noise ratio achievable. This limit is described by S/(N+D) = (6.02n + 1.76 + 10 log $F_S/2F_A$) dB, where n is the resolution of the converter in bits, F_S is the sampling frequency, and Fa is the signal bandwidth of interest. For audio bandwidth applications, the AD676 is capable of operating at a 2 × oversample rate (96 kSPS), which typically produces an improvement in S/(N+D) of 3 dB compared with operating at the Nyquist conversion rate of 48 kSPS. Oversampling has another advantage as well; the demands on the antialias filter are lessened. In summary, system performance is optimized by running the AD676 at or near its maximum sampling rate of 100 kHz and digitally filtering the resulting spectrum to eliminate undesired frequencies.

DC CODE UNCERTAINTY

Ideally, a fixed dc input should result in the same output code for repetitive conversions. However, as a consequence of system noise and circuit noise, for a given input voltage there is a range of output codes which may occur. Figure 9 is a histogram of the codes resulting from 1000 conversions of a typical input voltage by the AD676 used with a 5 V reference.

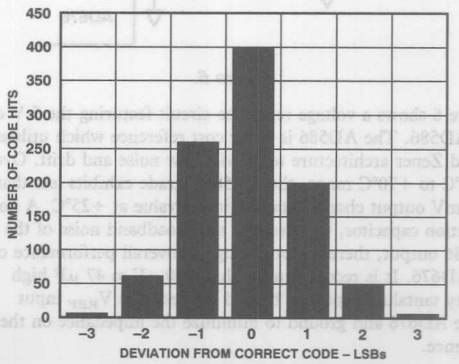

Figure 9. Distribution of Codes from 1000 Conversions, Relative to the Correct Code.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

The standard deviation of this distribution is approximately 1 LSB. If less uncertainty is desired, averaging multiple conversions will narrow this distribution by the inverse of the square root of the number of samples; i.e., the average of 4 conversions would have a standard deviation of 0.5 LSBs and the average of 16 conversions would have a standard deviation of 0.25 LSBs.

MICROPROCESSOR INTERFACE

The AD676 is ideally suited for use in both traditional dc measurement applications supporting a microprocessor, and in ac signal processing applications interfacing to a digital signal processor. The AD676 is designed to interface with a 16-bit data bus, providing all output data bits in a single read cycle. A variety of external buffers, such as 74HC541, can be used with the AD676 to provide 3-state outputs, high driving capability, and to prevent bus noise from coupling into the ADC. The following sections illustrate the use of the AD676 with a representative digital signal processor and microprocessor. These circuits provide general interface practices which are applicable to other processor choices.

ADSP-2101

Figure 10a shows the AD676 interfaced to the ADSP-2101 DSP processor. The AD676 buffers are mapped in the ADSP-2101's memory space, requiring one wait state when using a 12.5 MHz processor clock.

The falling edge of BUSY interrupts the processor, indicating that new data is ready. The ADSP-2101 automatically jumps to the appropriate service routine with minimal overhead. The interrupt routine then instructs the processor to read the new data using a memory read instruction.

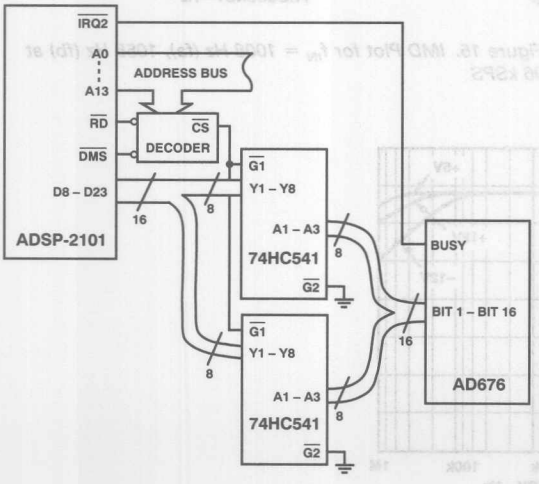

Figure 10a.

Figure 10b shows circuitry which would be included by a typical address decoder for the output buffers. In this case, a data memory access to any address in the range 3000H to 37FFH will result in the output buffers being enabled.

The AD676 CLK and SAMPLE can be generated by dividing down the system clock as described earlier (Figure 3), or if the ADSP-2101 serial port clocks are not being used, they can be programmed to generate CLK and SAMPLE.

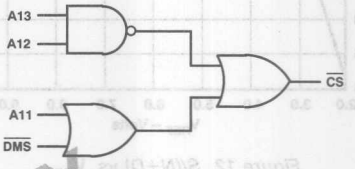

Figure 10b.

80286

The 80286 16-bit microprocessor can be interfaced to a buffered AD676 without any generation of wait states. As seen in Figure 11, BUSY can be used both to control the AD676 clock and to alert the processor when new data is ready. In the system shown, the 80286 should be configured in an edge triggered, direct interrupt mode (integrated controller provides the interrupt vector). Since the 80286 does not latch interrupt signals, the interrupt needs to be internally acknowledged before BUSY goes HIGH again during the next AD676 conversion (BUSY = 0). Depending on whether the AD676 buffers are mapped into memory or I/O space, the interrupt service routine will read the data by using either the MOV or the IN instruction. To be able to read all the 16 bits at once, and thereby increase the 80286's efficiency, the buffers should be located at an even address.

12-Bit 200 kSPS Complete Sampling ADC

AD678*

FEATURES

- AC and DC Characterized and Specified (K, B and T Grades)
- 200k Conversions per Second
- 1 MHz Full Power Bandwidth
- 500 kHz Full Linear Bandwidth
- 72 dB S/N+D (K, B, T Grades)
- Twos Complement Data Format (Bipolar Mode)
- Straight Binary Data Format (Unipolar Mode)
- 10 MΩ Input Impedance
- 8-Bit or 16-Bit Bus Interface
- On-Board Reference and Clock
- 10 V Unipolar or Bipolar Input Range
- Commercial, Industrial and Military Temperature Range Grades
- MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD678 is a complete, multipurpose 12-bit monolithic analog-to-digital converter, consisting of a sample-hold amplifier (SHA), a microprocessor compatible bus interface, a voltage reference and clock generation circuitry.

The AD678 is specified for ac (or "dynamic") parameters such as S/N+D ratio, THD and IMD which are important in signal processing applications. In addition, the AD678K, B and T grades are fully specified for dc parameters which are important in measurement applications.

The AD678 offers a choice of digital interface formats; the 12 data bits can be accessed by a 16-bit bus in a single read operation or by an 8-bit bus in two read operations (8+4), with right or left justification. Data format is straight binary for unipolar mode and twos complement binary for bipolar mode. The input has a full-scale range of 10 V with a full power bandwidth of 1 MHz and a full linear bandwidth of 500 kHz. High input impedance (10 MΩ) allows direct connection to unbuffered sources without signal degradation.

This product is fabricated on Analog Devices' BiMOS process, combining low power CMOS logic with high precision, low noise bipolar circuits; laser-trimmed thin-film resistors provide high accuracy. The converter utilizes a recursive subranging algorithm which includes error correction and flash converter circuitry to achieve high speed and resolution.

The AD678 operates from +5 V and ±12 V supplies and dissipates 560 mW (typ). The AD678 is available in 28-pin plastic DIP, ceramic DIP, and 44 J-leaded ceramic surface mount packages.

Screening to MIL-STD-883C Class B is also available.

***Protected by U.S. Patent Nos. 4,804,960; 4,814,767; 4,833,345; 4,250,445; 4,808,908; RE30,586.**

PRODUCT HIGHLIGHTS

1. COMPLETE INTEGRATION: The AD678 minimizes external component requirements by combining a high speed sample-hold amplifier (SHA), ADC, 5 V reference, clock and digital interface on a single chip. This provides a fully specified sampling A/D function unattainable with discrete designs.
2. SPECIFICATIONS: The AD678K, B and T grades provide fully specified and tested ac and dc parameters. The AD678J, A and S grades are specified and tested for ac parameters; dc accuracy specifications are shown as typicals. DC specifications (such as INL, gain and offset) are important in control and measurement applications. AC specifications (such as S/N+D ratio, THD and IMD) are of value in signal processing applications.
3. EASE OF USE: The pinout is designed for easy board layout, and the choice of single or two read cycle output provides compatibility with 16- or 8-bit buses. Factory trimming eliminates the need for calibration modes or external trimming to achieve rated performance.
4. RELIABILITY: The AD678 utilizes Analog Devices' monolithic BiMOS technology. This ensures long term reliability compared to multichip and hybrid designs.
5. UPGRADE PATH: The AD678 provides the same pinout as the 14-bit, 128 kSPS AD679 ADC.

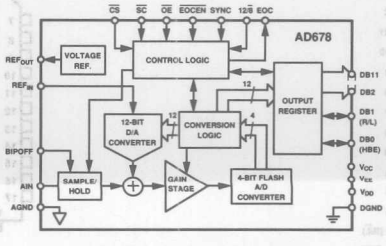
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

2

ESD SENSITIVITY

The AD678 features input protection circuitry consisting of large "distributed" diodes and polysilicon series resistors to dissipate both high energy discharges (Human Body Model) and fast, low energy pulses (Charged Device Model). Per Method 3015.2 of MIL-STD-883C, the AD678 has been classified as a Category 1 device.



Proper ESD precautions are strongly recommended to avoid functional damage or performance degradation. Charges as high as 4000 volts readily accumulate on the human body and test equipment and discharge without detection. Unused devices must be stored in conductive foam or shunts, and the foam should be discharged to the destination socket before devices are removed. For further information on ESD precautions, refer to Analog Devices' *ESD Prevention Manual*.

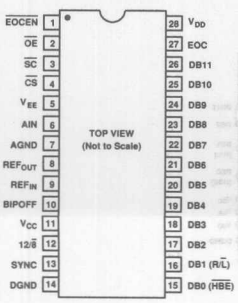
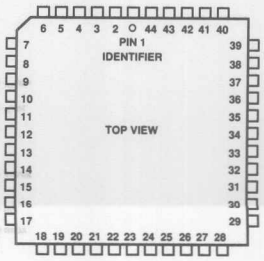
Functional Block Diagram



PIN DESCRIPTION

Symbol	28-Pin DIP Pin No.	44-Lead JLCC Pin No.	Type	Name and Function
AGND	7	11	P	Analog Ground. This is the ground return for AIN only.
AIN	6	10	AI	Analog Signal Input.
BIPOFF	10	15	AI	Bipolar Offset. Connect to AGND for +10 V input unipolar mode and straight binary output coding. Connect to REF_{OUT} through 50 Ω resistor for ±5 V input bipolar mode and twos complement binary output coding. See Figures 7 and 8.
$\overline{CS}$	4	6	DI	Chip Select. Active LOW.
DGND	14	23	P	Digital Ground
DB11–DB4	26–19	40, 39, 37, 36 35, 34, 33, 31	DO	Data Bits 11 through 4. In 12-bit format (see 12/$\overline{8}$ pin), these pins provide the upper 8 bits of data. In 8-bit format, these pins provide all 12 bits in two bytes (see R/$\overline{L}$ pin). Active HIGH.
DB3, DB2	18, 17	30, 27	DO	Data Bits 3 and 2. In 12-bit format, these pins provide Data Bit 3 and Data Bit 2. Active HIGH. In 8-bit format they are undefined and should be tied to V_{DD}.
DB1 (R/$\overline{L}$)	16	26	DO	In 12-bit format, Data Bit 1. Active HIGH.
DB0 ($\overline{HBE}$)	15	25	DO	In 12-bit format, Data Bit 0. Active HIGH.
EOC	27	42	DO	End-of-Convert. EOC goes LOW when a conversion starts and goes HIGH when the conversion is finished. In asynchronous mode, EOC is an open drain output and requires an external 3 kΩ pull-up resistor. See $\overline{EOCEN}$ and SYNC pins for information on EOC gating.
$\overline{EOCEN}$	1	1	DI	End-Of-Convert Enable. Enables EOC pin. Active LOW.
$\overline{HBE}$ (DB0)	15	25	DI	In 8-bit format, High Byte Enable. If LOW, output contains high byte. If HIGH, output contains low byte.
$\overline{OE}$	2	3	DI	Output Enable. The falling edge of $\overline{OE}$ enables DB11–DB0 in 12-bit format and DB11–DB4 in 8-bit format. Gated with $\overline{CS}$. Active LOW.
REF_{IN}	9	14	AI	Reference Input. +5 V input gives 10 V full scale range.
REF_{OUT}	8	12	AO	+5 V Reference Output. Tied to REF_{IN} through 50 Ω resistor for normal operation.
R/$\overline{L}$ (DB1)	16	26	DI	In 8-bit format, Right/Left justified. Sets alignment of 12-bit result within 16-bit field. Tied to V_{DD} for right-justified output and tied to DGND for left-justified output.
$\overline{SC}$	3	5	DI	Start Convert. Active LOW. See SYNC pin for gating.
SYNC	13	21	DI	SYNC Control. If tied to V_{DD} (synchronous mode), $\overline{SC}$, EOC and $\overline{EOCEN}$ are gated by $\overline{CS}$. If tied to DGND (asynchronous mode), $\overline{SC}$ and $\overline{EOCEN}$ are independent of $\overline{CS}$, and EOC is an open drain output. EOC requires an external 3 kΩ pull-up resistor in asynchronous mode.
V_{CC}	11	17	P	+12 V Analog Power.
V_{EE}	5	8	P	−12 V Analog Power.
V_{DD}	28	43	P	+5 V Digital Power.
12/$\overline{8}$	12	19	DI	Twelve/eight bit format. If tied HIGH, sets output format to 12-bit parallel. If tied LOW, sets output format to 8-bit multiplexed.
No Connect	—	2, 4, 7, 9, 13, 16, 18, 20, 22, 24, 28, 29, 32, 38, 41, 44	—	These pins are unused and should be connected to DGND or V_{DD}.



Type: AI = Analog Input; AO = Analog Output; DI = Digital Input (TTL and 5 V CMOS compatible); DO = Digital Output (TTL and 5 V CMOS compatible). All DO pins are three-state drivers; P = Power.

PIN CONFIGURATIONS

DIP PACKAGE

JLCC PACKAGE

NYQUIST FREQUENCY
An implication of the Nyquist sampling theorem, the "Nyquist Frequency" of a converter is that input frequency which is one-half the sampling frequency of the converter.

SIGNAL-TO-NOISE AND DISTORTION (S/N+D) RATIO
S/N+D is the ratio of the rms value of the measured input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc.

TOTAL HARMONIC DISTORTION (THD)
THD is the ratio of the rms sum of the first six harmonic components to the rms value of a full-scale input signal and is expressed as a percentage or in decibels. For input signals or harmonics that are above the Nyquist frequency, the aliased component is used.

PEAK SPURIOUS OR PEAK HARMONIC COMPONENT
The peak spurious or peak harmonic component is the largest spectral component excluding the input signal and dc. This value is expressed in decibels relative to the rms value of a full-scale input signal.

INTERMODULATION DISTORTION (IMD)
With inputs consisting of sine waves at two frequencies, fa and fb, any device with nonlinearities will create distortion products, of order (m + n), at sum and difference frequencies of mfa ± nfb, where m, n = 0, 1, 2, 3 . . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are (fa + fb) and (fa − fb) and the third order terms are (2 fa + fb), (2 fa − fb), (fa + 2 fb) and (fa − 2 fb). The IMD products are expressed as the decibel ratio of the rms sum of the measured input signals to the rms sum of the distortion terms. The two signals applied to the converter are of equal amplitude and the peak value of their sum is −0.5 dB from full scale (9.44 V p-p). The IMD products are normalized to a 0 dB input signal.

BANDWIDTH
The full-power bandwidth is that input frequency at which the amplitude of the reconstructed fundamental is reduced by 3 dB for a full-scale input.

The full-linear bandwidth is the input frequency at which the slew rate limit of the sample-hold-amplifier (SHA) is reached. At this point, the amplitude of the reconstructed fundamental has degraded by less than −0.1 dB. Beyond this frequency, distortion of the sampled input signal increases significantly.

The AD678 has been designed to optimize input bandwidth, allowing the AD678 to undersample input signals with frequencies significantly above the converter's Nyquist frequency.

APERTURE DELAY
Aperture delay is a measure of the SHA's performance and is measured from the falling edge of Start Convert ($\overline{SC}$) to when the input signal is held for conversion. In synchronous mode, Chip Select ($\overline{CS}$) should be LOW before $\overline{SC}$ to minimize aperture delay.

APERTURE JITTER
Aperture jitter is the variation in aperture delay for successive samples and is manifested as noise on the input to the A/D.

INPUT SETTLING TIME
Settling time is a function of the SHA's ability to track fast slewing signals. This is specified as the maximum time required in track mode after a full-scale step input to guarantee rated conversion accuracy.

DIFFERENTIAL NONLINEARITY (DNL)
In an ideal ADC, code transitions are 1LSB apart. Differential nonlinearity is the maximum deviation from this ideal value. It is often specified in terms of resolution for which no missing codes (NMC) are guaranteed.

UNIPOLAR ZERO ERROR
In unipolar mode, the first transition should occur at a level 1/2 LSB above analog ground. Unipolar zero error is the deviation of the actual transition from that point. This error can be adjusted as discussed in the Input Connections and Calibration section.

BIPOLAR ZERO ERROR
In the bipolar mode, the major carry transition (1111 1111 1111 to 0000 0000 0000) should occur at an analog value 1/2 LSB below analog ground. Bipolar zero error is the deviation of the actual transition from that point. This error can be adjusted as discussed in the Input Connections and Calibration section.

GAIN ERROR
The last transition should occur at an analog value 1 1/2 LSB below the nominal full scale (9.9963 volts for a 0–10 V range, 4.9963 volts for a ±5 V range). The gain error is the deviation of the actual difference between the first and last code transition from the ideal difference between the first and last code transition. This error can be adjusted as shown in the Input Connections and Calibration section.

INTEGRAL NONLINEARITY (INL)
The ideal transfer function for a linear ADC is a straight line drawn between "zero" and "full scale." The point used as "zero" occurs 1/2LSB before the first code transition. "Full scale" is defined as a level 1 1/2LSB beyond the last code transition. Integral nonlinearity is the worst-case deviation of a code from the straight line. The deviation of each code is measured from the middle of that code.

POWER SUPPLY REJECTION
Variations in power supply will affect the full-scale transition, but not the converter's linearity. Power Supply Rejection is the maximum change in the full-scale transition point due to a change in power-supply voltage from the nominal value.

TEMPERATURE DRIFT
This is the maximum change in the parameter from the initial value (@ 25°C) to the value at T_{min} or T_{max}.

CONVERSION CONTROL

In synchronous mode (SYNC = HIGH), both Chip Select ($\overline{CS}$) and Start Convert ($\overline{SC}$) must be brought LOW to start a conversion. $\overline{CS}$ should be LOW t_{SC} before $\overline{SC}$ is brought LOW. In asynchronous mode (SYNC = LOW), a conversion is started by bringing $\overline{SC}$ low, regardless of the state of $\overline{CS}$.

Before a conversion is started, End-of-Convert (EOC) is HIGH, and the sample-hold is in track mode. After a conversion is started, the sample-hold goes into hold mode and EOC goes LOW, signifying that a conversion is in progress. During the conversion, the sample-hold will go back into track mode and start acquiring the next sample. EOC goes HIGH when the conversion is finished.

In track mode, the sample-hold will settle to ±0.01% (12 bits) in 1 µs maximum. The acquisition time does not affect the throughput rate as the AD678 goes back into track mode more than 1 µs before the next conversion. In multichannel systems, the input channel can be switched as soon as EOC goes LOW if the maximum throughput rate is needed.

12-BIT MODE CODING FORMAT (1 LSB = 2.44 mV)

Unipolar Coding (Straight Binary)		Bipolar Coding (Twos Complement)	
V_{IN}*	Output Code	V_{IN}*	Output Code

END-OF-CONVERT

In asynchronous mode, End-of-Convert (EOC) is an open drain output (requiring a minimum 3 kΩ pull-up resistor) enabled by End-of-Convert ENable ($\overline{EOCEN}$). In synchronous mode, EOC is a three-state output which is enabled by $\overline{EOCEN}$ and $\overline{CS}$. See the Conversion Status Truth Table for details. Access (t_{BA}) and float (t_{FD}) timing specifications do not apply in asynchronous mode where they are a function of the time constant formed by the 10 pF output capacitance and the pull-up resistor.

0 = LOW voltage level.
X = Don't care.
*EOC requires a pull-up resistor in asynchronous mode.

OUTPUT ENABLE OPERATION

The data bits (DB11–DB0) are three-state outputs enabled by Chip Select ($\overline{CS}$) and Output Enable ($\overline{OE}$). $\overline{CS}$ should be LOW t_{OE} before $\overline{OE}$ is brought LOW. Bits DB1 (R/$\overline{L}$) and DB0 ($\overline{HBE}$) are bidirectional. In 12-bit mode they are data output bits. In 8-bit mode they are inputs which define the format of the output register.

In unipolar mode (BIPOFF tied to AGND), the output coding is straight binary. In bipolar mode (BIPOFF tied to REF_{OUT}), output coding is twos complement binary.

When EOC goes HIGH, the conversion is completed and the output data may be read. Bringing $\overline{OE}$ LOW t_{OE} after $\overline{CS}$ is brought LOW makes the output register contents available on the data bits. A period of time t_{CD} is required after $\overline{OE}$ is brought HIGH before the next $\overline{SC}$ instruction may be issued.

Figure 10 illustrates the 8-bit read mode (12/$\overline{8}$ = LOW), where only DB11–DB4 are used as output lines onto an 8-bit bus. The output is read in two steps, with the high byte read first, followed by the low byte. High Byte Enable ($\overline{HBE}$) controls the output sequence. The 12-bit result can be right or left justified depending on the state of R/$\overline{L}$.

In 12-bit read mode (12/$\overline{8}$ = HIGH), a single READ operation accesses all 12 output bits on DB11–DB0 for interface to a 16-bit bus. Figure 11 provides the output timing relationships. Note that t_{CR} must be observed, in that $\overline{SC}$ pulses should not be issued at intervals closer than 5 μs. If $\overline{SC}$ is asserted sooner than 5 μs, conversion accuracy may deteriorate. For this reason, $\overline{SC}$ should not be held LOW in an attempt to operate in a continuously converting mode.

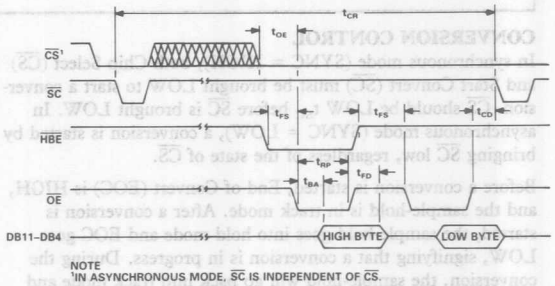

Figure 10. Output Timing, 8-Bit Read Mode

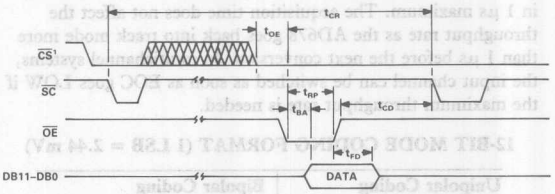

Figure 11. Output Timing, 12-Bit Read Mode

POWER-UP

The AD678 typically requires 10 μs after power-up to reset internal logic.

Application Information

INPUT CONNECTIONS AND CALIBRATION

The high (10 MΩ) input impedance of the AD678 eases the task of interfacing to high source impedances or multiplexer channel-to-channel mismatches of up to 1000 Ω. The 10 V p-p full-scale input range accepts the majority of signal voltages without the need for voltage divider networks which could deteriorate the accuracy of the ADC.

The AD678 is factory trimmed to minimize linearity, offset and gain errors. In unipolar mode, the only external component that is required is a 50 Ω ±1% resistor. Two resistors are required in bipolar mode. If offset and gain are not critical (as in some ac applications), even these components can be eliminated.

In some applications, offset and gain errors need to be trimmed out completely. The following sections describe the correct procedure for these various situations.

UNIPOLAR RANGE INPUTS

Offset and gain errors can be trimmed out by using the configuration shown in Figure 12. This circuit allows approximately ±25 mV of offset trim range (±10 LSB) and ±0.5% of gain trim (±20 LSB).

The first transition (from 0000 0000 0000 to 0000 0000 0001) should nominally occur for an input level of +1/2 LSB (1.22 mV above ground for a 10 V range). To trim unipolar zero to this nominal value, apply a 1.22 mV signal to AIN and adjust R1 until the first transition is located.

The gain trim is done by adjusting R2. If the nominal value is required, apply a signal 1 1/2 LSB below full scale (9.9963 V for a 10 V range) and adjust R2 until the last transition is located (1111 1111 1110 to 1111 1111 1111).

If offset adjustment is not required, BIPOFF should be connected directly to AGND. If gain adjustment is not required, R2 should be replaced with a fixed 50 Ω ±1% metal film resistor. If REF_{OUT} is connected directly to REF_{IN}, the additional gain error will be approximately 1%.

BIPOLAR RANGE INPUTS

The connections for the bipolar mode are shown in Figure 13. In this mode, data output coding will be in twos-complement binary. This circuit will allow approximately ±25 mV of offset trim range (±10 LSB) and ±0.5% of gain trim range (20 LSB).

Either or both of the trim pots can be replaced with 50 Ω ± 1% fixed resistors if the AD678 accuracy limits are sufficient for the application. If the pins are shorted together, the additional offset and gain errors will be approximately 1%.

To trim bipolar zero to its nominal value, apply a signal 1/2 LSB below midrange (−1.22 mV for a ±5 V range) and adjust R1 until the major carry transition is located (1111 1111 1111 to 0000 0000 0000). To trim the gain, apply a signal 1 1/2 LSB below full scale (+4.9963 V for a ±5 V range) and adjust R2 to give the last positive transition (0111 1111 1110 to 0111 1111 1111). These trims are interactive so several iterations may be necessary for convergence.

A single-pass calibration can be done by substituting a bipolar offset trim (error at minus full scale) for the bipolar zero trim (error at midscale), using the same circuit. First, apply a signal 1/2 LSB above minus full scale (−4.9988 V for a ±5 V range) and adjust R1 until the minus full-scale transition is located (1000 0000 0000 to 1000 0000 001). Then perform the gain error trim as outlined above.

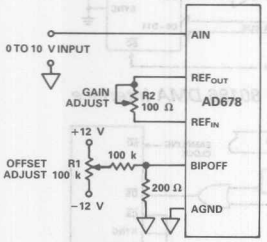

Figure 12. Unipolar Input Connections with Gain and Offset Trims

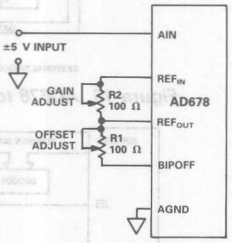

Figure 13. Bipolar Input Connections with Gain and Offset Trims

BOARD LAYOUT

Designing with high-resolution data converters requires careful attention to layout. Trace impedance is a significant issue. At the 12-bit level, a 5 mA current through a 0.5 Ω trace will develop a voltage drop of 2.5 mV, which is 1 LSB for a 10 V full-scale span. In addition to ground drops, inductive and capacitive coupling need to be considered, especially when high-accuracy analog signals share the same board with digital signals. Finally, power supplies need to be decoupled in order to filter out ac noise.

Analog and digital signals should not share a common path. Each signal should have an appropriate analog or digital return routed close to it. Using this approach, signal loops enclose a small area, minimizing the inductive coupling of noise. Wide PC tracks, large gauge wire, and ground planes are highly recommended to provide low impedance signal paths. Separate analog and digital ground planes are also desirable, with a single interconnection point to minimize ground loops. Analog signals should be routed as far as possible from digital signals and should cross them at right angles.

The AD678 incorporates several features to help the user's layout. Analog pins (V_{EE}, AIN, AGND, REF_{OUT}, REF_{IN}, BIPOFF, V_{CC}) are adjacent to help isolate analog from digital signals. In addition, the 10 MΩ input impedance of AIN minimizes input trace impedance errors. Finally, ground currents have been minimized by careful circuit design. Current through AGND is 200 μA, with no code-dependent variation. The current through DGND is dominated by the return current for DB11–DB0 and EOC.

SUPPLY DECOUPLING

The AD678 power supplies should be well filtered, well regulated, and free from high-frequency noise. Switching power supplies are not recommended. These supplies generate spikes which can induce noise in the analog system.

Decoupling capacitors should be located as close as possible to all power supply pins. A 10 μF tantalum capacitor in parallel with a 0.1 μF ceramic provides adequate decoupling. The power supply pins should be decoupled directly to AGND.

An effort should be made to minimize the trace length between the capacitor leads and the respective converter power supply and common pins. The circuit layout should attempt to locate the AD678, associated analog input circuitry and interconnections as far as possible from logic circuitry. A solid analog ground plane around the AD678 will isolate large switching ground currents. For these reasons, the use of wire wrap circuit construction is not recommended; careful printed circuit construction is preferred.

GROUNDING

If a single AD678 is used with separate analog and digital ground planes, connect the analog ground plane to AGND and the digital ground plane to DGND keeping lead lengths as short as possible. Then connect AGND and DGND together at the AD678. If multiple AD678s are used or the AD678 shares analog supplies with other components, connect the analog and digital returns together once at the power supplies rather than at each chip. This prevents large ground loops which inductively couple noise and allow digital currents to flow through the analog system.

INTERFACING THE AD678 TO MICROPROCESSORS

The I/O capabilities of the AD678 allow direct interfacing to general purpose and DSP microprocessor buses. The asynchronous conversion control feature allows complete flexibility and control with minimal external hardware.

The following examples illustrate typical AD678 interface configurations.

space. AD678 conversions are initiated by issuing an OUT instruction to Port 8. EOC status and the conversion result are read in with an IN instruction to Port 8. A single wait state is inserted by generating the processor READY input from $\overline{IS}$, Port 8 and $\overline{MSC}$. This configuration supports processor clock speeds of 20 MHz and is capable of supporting processor clock speeds of 40 MHz if a NOP instruction follows each AD678 read instruction.

AD678 TO 80186

Figure 15 shows the AD678 interfaced to the 80186 microprocessor. This interface allows the 80186's built-in DMA controller to transfer the AD678 output into a RAM based FIFO buffer of any length, with no microprocessor intervention.

In this application the AD678 is configured in the asynchronous mode, which allows conversions to be initiated by an external trigger source independent of the microprocessor clock. After each conversion, the AD678 EOC signal generates a DMA request to Channel 1 (DRQ1). The subsequent DMA READ operation resets the interrupt latch. The system designer must assign a sufficient priority to the DMA channel to ensure that the DMA request will be serviced before the completion of the next conversion. This configuration can be used with 6-MHz and 8-MHz 80186 processors.

AD678 TO ANALOG DEVICES ADSP-2101

Figure 16 demonstrates the AD678 interfaced to an ADSP-2101. With a clock frequency of 12.5 MHz, and instruction execution in one 80 ns cycle, the digital signal processor supports the AD678 interface with one wait state.

The converter is configured to run asynchronously using a sampling clock. The EOC output of the AD678 gets asserted at the end of each conversion and causes an interrupt. Upon interrupt, the ADSP-2101 immediately asserts its FO pin LOW. In the following cycle, the processor starts a data memory read by providing an address on the DMA bus. The decoded address generates $\overline{OE}$ for the converter, and the high byte of the conversion result is read over the data bus. The read operation is extended with one wait state and thus started and completed within two processor cycles (160 ns). Next, the ADSP-2101 asserts its FO pin HIGH. This allows the processor to start reading the lower byte of data. This read operation executes in a similar manner to the first and is completed during the next 160 ns.

AD678 TO ANALOG DEVICES ADSP-2100A

Figure 17 demonstrates the AD678 interfaced to an ADSP-2100A. With a clock frequency of 12.5 MHz, and instruction execution in one 80 ns cycle, the digital signal processor will support the AD678 data memory interface with three hardware wait states.

The converter is configured to run asynchronously using a sampling clock. The EOC output of the AD678 gets asserted at the end of each conversion and causes an interrupt. Upon interrupt, the ADSP-2100A immediately executes a data memory write instruction which asserts $\overline{HBE}$. In the following cycle, the processor starts a data memory read (high byte read) by providing an address on the DMA bus. The decoded address generates $\overline{OE}$ for the converter. $\overline{OE}$, together with logic and latch, is used to force the ADSP-2100A into a one cycle wait state by generating DMACK. The read operation is thus started and completed within two processor cycles (160 ns). $\overline{HBE}$ is released during "high byte read." This allows the processor to read the lower

is completed during the next 160 ns.

AD679*

FEATURES

- AC and DC Characterized and Specified (K, B, T Grades)
- 128k Conversions per Second
- 1 MHz Full Power Bandwidth
- 500 kHz Full Linear Bandwidth
- 80 dB S/N+D (K, B, T Grades)
- Twos Complement Data Format (Bipolar Mode)
- Straight Binary Data Format (Unipolar Mode)
- 10 MΩ Input Impedance
- 8-Bit Bus Interface (See AD779 for 16-Bit Interface)
- On-Board Reference and Clock
- 10 V Unipolar or Bipolar Input Range
- Pin Compatible with AD678 12-Bit, 200 kSPS ADC
- MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD679 is a complete, multipurpose 14-bit monolithic analog-to-digital converter, consisting of a sample-hold amplifier (SHA), a microprocessor compatible bus interface, a voltage reference and clock generation circuitry.

The AD679 is specified for ac (or "dynamic") parameters such as S/N+D ratio, THD and IMD which are important in signal processing applications. In addition, the AD679K, B and T grades are fully specified for dc parameters which are important in measurement applications.

The 14 data bits are accessed in two read operations (8+6), with left justification. Data format is straight binary for unipolar mode and twos complement binary for bipolar mode. The input has a full-scale range of 10 V with a full power bandwidth of 1 MHz and a full linear bandwidth of 500 kHz. High input impedance (10 MΩ) allows direct connection to unbuffered sources without signal degradation. Conversions can be initiated either under microprocessor control or by an external clock asynchronous to the system clock.

This product is fabricated on Analog Devices' BiMOS process, combining low power CMOS logic with high precision, low noise bipolar circuits; laser-trimmed thin-film resistors provide high accuracy. The converter utilizes a recursive subranging algorithm which includes error correction and flash converter circuitry to achieve high speed and resolution.

The AD679 operates from +5 V and ±12 V supplies and dissipates 560 mW (typ.). 28-pin plastic DIP, ceramic DIP and 44 J-leaded ceramic surface mount packages are available.

***Protected by U.S. Patent Nos. 4,804,960; 4,814,767; 4,833,345; 4,250,445; 4,808,908; RE 30,586**

PRODUCT HIGHLIGHTS

1. COMPLETE INTEGRATION: The AD679 minimizes external component requirements by combining a high speed sample-hold amplifier (SHA), ADC, 5 V reference, clock and digital interface on a single chip. This provides a fully specified sampling A/D function unattainable with discrete designs.
2. SPECIFICATIONS: The AD679K, B and T grades provide fully specified and tested ac and dc parameters. The AD679J, A and S grades are specified and tested for ac parameters; dc accuracy specifications are shown as typicals. DC specifications (such as INL, gain and offset) are important in control and measurement applications. AC specifications (such as S/N+D ratio, THD and IMD) are of value in signal processing applications.
3. EASE OF USE: The pinout is designed for easy board layout, and the two read output provides compatibility with 8-bit buses. Factory trimming eliminates the need for calibration modes or external trimming to achieve rated performance.
4. RELIABILITY: The AD679 utilizes Analog Devices' monolithic BiMOS technology. This ensures long term reliability compared to multichip and hybrid designs.
5. UPGRADE PATH: The AD679 provides the same pinout as the 12-bit, 200 kSPS AD678 ADC.
6. The AD679 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD679/883B data sheet for detailed specifications.

AD679—SPECIFICATIONS

AC SPECIFICATIONS (T_{MIN} to T_{MAX}, V_{CC} = +12 V ± 5%, V_{EE} = −12 V ± 5%, V_{DD} = +5 V ± 10%, f_{SAMPLE} = 128 kSPS, f_{IN} = 10.009 kHz unless otherwise noted)[1]

NOTES
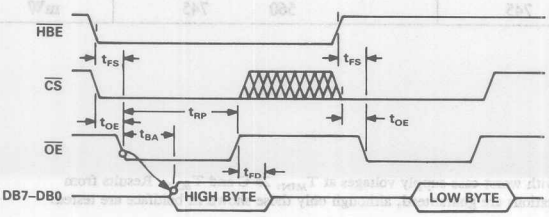
[1]Includes Acquisition Time.
[2]Measured from the falling edge of $\overline{OE}$/$\overline{EOCEN}$ (0.8 V) to the time at which the data lines/EOC cross 2.0 V or 0.8 V. See Figure 4.
[3]C_{OUT} = 100 pF.
[4]C_{OUT} = 50 pF.
[5]Measured from the rising edge of $\overline{OE}$/$\overline{EOCEN}$ (2.0 V) to the time at which the output voltage changes by 0.5. See Figure 4; C_{OUT} = 10 pF.

Specifications shown in **boldface** are tested on all devices at final electrical test with worst case supply voltages at T_{MIN}, +25°C and T_{MAX}. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested.

Specifications subject to change without notice.

NOTES
[1]IN ASYNCHRONOUS MODE, STATE OF $\overline{CS}$ DOES NOT AFFECT OPERATION. SEE THE START CONVERSION TRUTH TABLE FOR DETAILS.
[2]$\overline{EOCEN}$ = LOW (SEE FIGURE 3). IN SYNCHRONOUS MODE, EOC IS A THREE-STATE OUTPUT. IN ASYNCHRONOUS MODE, EOC IS AN OPEN DRAIN OUTPUT.
[3]DATA SHOULD NOT BE ENABLED DURING A CONVERSION.

Figure 1. Conversion Timing



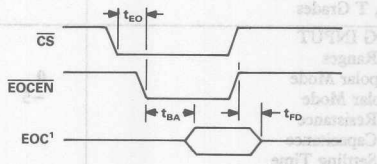


Figure 2. Output Timing

NOTE
[1]EOC IS A THREE-STATE OUTPUT IN SYNCHRONOUS MODE AND AN OPEN DRAIN OUTPUT IN ASYNCHRONOUS. ACCESS (t_{BA}) AND FLOAT (t_{FD}) TIMING SPECIFICATIONS DO NOT APPLY IN ASYNCHRONOUS MODE WHERE THEY ARE A FUNCTION THE TIME CONSTANT FORMED BY THE 10 pF OUTPUT CAPACITANCE AND THE PULL-UP RESISTOR.

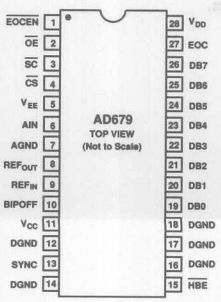
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

2

ESD SENSITIVITY

The AD679 features input protection circuitry consisting of large "distributed" diodes and polysilicon series resistors to dissipate both high energy discharges (Human Body Model) and fast, low energy pulses (Charged Device Model). Per Method 3015.2 of MIL-STD-883C, the AD679 has been classified as a Category 1 device.

Proper ESD precautions are strongly recommended to avoid functional damage or performance degradation. Charges as high as 4000 volts readily accumulate on the human body and test equipment and discharge without detection. Unused devices must be stored in conductive foam or shunts, and the foam should be discharged to the destination socket before devices are removed. For further information on ESD precautions, refer to Analog Devices' *ESD Prevention Manual*.



ORDERING GUIDE

Model	Package	Temperature Range	Tested and Specified	Package Option*
AD679JN	28-Pin Plastic DIP	0°C to +70°C	AC	N-28
AD679KN	28-Pin Plastic DIP	0°C to +70°C	AC + DC	N-28
AD679JD	28-Pin Ceramic DIP	0°C to +70°C	AC	D-28A

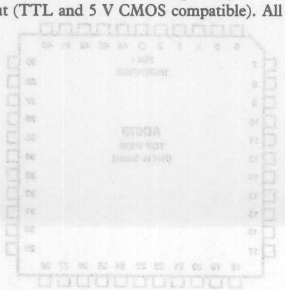
*N = Plastic DIP; D = Ceramic DIP; J = J-Leaded Ceramic Chip Carrier. For outline information, see Package Information section.

PIN CONFIGURATION

DIP Package



JLCC Package

PIN DESCRIPTION

Symbol	28-Pin DIP Pin No.	44-Lead JLCC Pin No.	Type	Name and Function
AGND	7	11	P	Analog Ground. This is the ground return for AIN only.
AIN	6	10	AI	Analog Signal Input.
BIPOFF	10	15	AI	Bipolar Offset. Connect to AGND for +10 V input unipolar mode and straight binary output coding. Connect to REF_{OUT} for ±5 V input bipolar mode and twos complement binary output coding.
$\overline{CS}$	4	6	DI	Chip Select. Active LOW.
DGND	12, 14	23	P	Digital Ground.
DB7–DB0	26–19	40, 39, 37 36, 35, 34 33, 31	DO	Data Bits. These pins provide all 14 bits in two bytes (8+6 bits). Active HIGH.
EOC	27	42	DO	End-of-Convert. EOC goes LOW when a conversion starts and goes HIGH when the conversion finishes. In asynchronous mode, EOC is an open drain output and requires an external 3 kΩ pull-up resistor. See $\overline{EOCEN}$ and SYNC pins for information on EOC gating.
$\overline{EOCEN}$	1	1	DI	End-of-Convert Enable. Enables EOC pin. Active LOW.
$\overline{HBE}$	15	25	DI	High Byte Enable. If LOW, output contains high byte. If HIGH, output contains low byte (corresponding to the most recently read high byte).
$\overline{OE}$	2	3	DI	Output Enable. A down-going transition on $\overline{OE}$ enables DB7–DB0. Gated with $\overline{CS}$. Active LOW.
REF_{IN}	9	14	AI	Reference Input. +5 V input gives 10 V full scale range.
REF_{OUT}	8	12	AO	+5 V Reference Output. Tied to REF_{IN} for normal operation.
$\overline{SC}$	3	5	DI	Start Convert. Active LOW. See SYNC pin for gating.
SYNC	13	21	DI	SYNC Control. If tied to V_{DD} (synchronous mode), $\overline{SC}$ and $\overline{EOCEN}$ are gated by $\overline{CS}$. If tied to DGND (asynchronous mode), $\overline{SC}$ and $\overline{EOCEN}$ are independent of $\overline{CS}$, and EOC is an open drain output. EOC requires an external 3 kΩ pull-up resistor in asynchronous mode.
V_{CC}	11	17	P	+12 V Analog Power.
V_{EE}	5	8	P	−12 V Analog Power.
V_{DD}	28	43	P	+5 V Digital Power.
—	16		U	Tie to DGND.
—	17–18	2, 4, 7, 9, 13 16, 18, 19, 20, 22, 24, 26, 27, 28, 29, 30, 32, 38, 41, 44	U	These pins are unused and should be connected to DGND or V_{DD}.

Type: AI = Analog Input.
AO = Analog Output.
DI = Digital Input (TTL and 5 V CMOS compatible).
DO = Digital Output (TTL and 5 V CMOS compatible). All DO pins are three-state drivers.
P = Power.
U = Unused.

NYQUIST FREQUENCY
An implication of the Nyquist sampling theorem, the "Nyquist Frequency" of a converter is that input frequency which is one-half the sampling frequency of the converter.

SIGNAL-TO-NOISE AND DISTORTION (S/N+D) RATIO
S/N+D is the ratio of the rms value of the measured input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc.

TOTAL HARMONIC DISTORTION (THD)
THD is the ratio of the rms sum of the first six harmonic components to the rms value of a full-scale input signal and is expressed as a percentage or in decibels. For input signals or harmonics that are above the Nyquist frequency, the aliased component is used.

PEAK SPURIOUS OR PEAK HARMONIC COMPONENT
The peak spurious or peak harmonic component is the largest spectral component excluding the input signal and dc. This value is expressed in decibels relative to the rms value of a full-scale input signal.

INTERMODULATION DISTORTION (IMD)
With inputs consisting of sine waves at two frequencies, fa and fb, any device with nonlinearities will create distortion products, of order (m + n), at sum and difference frequencies of mfa ± nfb, where m, n = 0, 1, 2, 3 . . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are (fa + fb) and (fa − fb) and the third order terms are (2 fa + fb), (2 fa − fb), (fa + 2 fb) and (fa − 2 fb). The IMD products are expressed as the decibel ratio of the rms sum of the measured input signals to the rms sum of the distortion terms. The two signals applied to the converter are of equal amplitude and the peak value of their sum is −0.5 dB from full scale (9.44 V p–p). The IMD products are normalized to a 0-dB input signal.

BANDWIDTH
The full-power bandwidth is that input frequency at which the amplitude of the reconstructed fundamental is reduced by 3 dB for a full-scale input.

The full-linear bandwidth is the input frequency at which the slew rate limit of the sample-hold-amplifier (SHA) is reached. At this point, the amplitude of the reconstructed fundamental has degraded by less than −0.1 dB. Beyond this frequency, distortion of the sampled input signal increases significantly.

The AD679 has been designed to optimize input bandwidth, allowing it to undersample input signals with frequencies significantly above the converter's Nyquist frequency.

APERTURE DELAY
Aperture delay is a measure of the SHA's performance and is measured from the falling edge of Start Convert ($\overline{SC}$) to when the input signal is held for conversion. In synchronous mode, Chip Select ($\overline{CS}$) should be LOW before $\overline{SC}$ to minimize aperture delay.

APERTURE JITTER
Aperture jitter is the variation in aperture delay for successive samples and is manifested as noise on the input to the A/D.

INPUT SETTLING TIME
Settling time is a function of the SHA's ability to track fast slewing signals. This is specified as the maximum time required in track mode after a full-scale step input to guarantee rated conversion accuracy.

DIFFERENTIAL NONLINEARITY (DNL)
In an ideal ADC, code transitions are 1 LSB apart. Differential linearity is the deviation from this ideal value. It is often specified in terms of resolution for which no missing codes (NMC) are guaranteed.

INTEGRAL NONLINEARITY (INL)
The ideal transfer function for a linear ADC is a straight line drawn between "zero" and "full scale." The point used as "zero" occurs 1/2 LSB before the first code transition. "Full scale" is defined as a level 1 1/2 LSB beyond the last code transition. Integral linearity error is the worst case deviation of a code from the straight line. The deviation of each code is measured from the middle of that code.

Note that the linearity error is not user adjustable.

POWER SUPPLY REJECTION
Variations in power supply will affect the full-scale transition, but not the converter's linearity. Power Supply Rejection is the maximum change in the full-scale transition point due to a change in power supply voltage from the nominal value.

TEMPERATURE DRIFT
This is the maximum change in the parameter from the initial value (@+25°C) to the value at T_{MIN} or T_{MAX}.

UNIPOLAR ZERO ERROR
In unipolar mode, the first transition should occur at a level 1/2 LSB above analog ground. Unipolar zero error is the deviation of the actual transition from that point. This error can be adjusted as discussed in the Input Connections and Calibration section.

BIPOLAR ZERO ERROR
In the bipolar mode, the major carry transition (11 1111 1111 1111 to 00 0000 0000 0000) should occur at an analog value 1/2 LSB below analog ground. Bipolar zero error is the deviation of the actual transition from that point. This error can be adjusted as discussed in the Input Connections and Calibration section.

GAIN ERROR
The last transition should occur at an analog value 1 1/2 LSB below the nominal full scale (9.9991 volts for a 0–10 V range, 4.9991 volts for a ±5 V range). The gain error is the deviation of the actual level at the last transition from the ideal level with the zero error trimmed out. This error can be adjusted as shown in the Input Connections and Calibration section.

CONVERSION CONTROL

In synchronous mode (SYNC = HIGH), both Chip Select ($\overline{CS}$) and Start Convert ($\overline{SC}$) must be brought LOW to start a conversion. $\overline{CS}$ should be LOW t_{SC} before $\overline{SC}$ is brought LOW. In asynchronous mode (SYNC = LOW), a conversion is started by bringing $\overline{SC}$ low, regardless of the state of $\overline{CS}$.

Before a conversion is started, End-of-Convert (EOC) is HIGH and the sample-hold is in track mode. After a conversion is started, the sample-hold goes into hold mode and EOC goes LOW, signifying that a conversion is in progress. During the conversion, the sample-hold will go back into track mode and start acquiring the next sample.

In track mode, the sample-hold will settle to ±0.003% (14 bits) in 1.5 µs maximum. The acquisition time does not affect the throughput rate as the AD679 goes back into track mode more than 2 µs before the next conversion. In multichannel systems, the input channel can be switched as soon as EOC goes LOW.

Bringing $\overline{OE}$ LOW t_{OE} after $\overline{CS}$ goes LOW makes the output register contents available on the output data bits (DB7–DB0). A period of time t_{CD} is required after $\overline{OE}$ is brought HIGH before the next $\overline{SC}$ instruction is issued.

If $\overline{SC}$ is held LOW, conversion accuracy may deteriorate. For this reason, $\overline{SC}$ should not be held low in an attempt to operate in a continuously converting mode.

START CONVERSION TRUTH TABLE

	INPUTS			
	SYNC	$\overline{CS}$	$\overline{SC}$	STATUS
Synchronous Mode	1	1	X	No Conversion
	1	0	↓	Start Conversion
	1	↓	0	Start Conversion (Not Recommended)
	1	0	0	Continuous Conversion (Not Recommended)
Asynchronous Mode	0	X	1	No Conversion
	0	X	↓	Start Conversion
	0	X	0	Continuous Conversion (Not Recommended)

NOTES
1 = HIGH voltage level.
0 = LOW voltage level.
X = Don't care.
↓ = HIGH to LOW transition. Must stay low for $t = t_{CP}$.

14-BIT MODE CODING FORMAT (1 LSB = 0.61 mV)

Unipolar Coding (Straight Binary)		Bipolar Coding (Twos Complement)	
V_{IN}*	Output Code	V_{IN}*	Output Code
0.00000 V	000 . . . 0	−5.00000 V	100 . . . 0
5.00000 V	100 . . . 0	−0.00061 V	111 . . . 1

		+2.50000 V	010 . . . 0
		+4.99939 V	011 . . . 1

*Code center.

END-OF-CONVERT

In asynchronous mode, End-of-Convert (EOC) is an open drain output (requiring a minimum 3 kΩ pull-up resistor) enabled by End-of-Convert Enable ($\overline{EOCEN}$). In synchronous mode, EOC is a three-state output which is enabled by $\overline{EOCEN}$ and $\overline{CS}$. See Conversion Status Truth Table. Access (t_{BA}) and float (t_{FD}) timing specifications do not apply in asynchronous mode where they are a function of the time constant formed by the external load capacitance and the pull-up resistor.

OUTPUT ENABLE OPERATION

The data bits (DB7–DB0) are three-state outputs that are enabled by Chip Select ($\overline{CS}$) and Output Enable ($\overline{OE}$). $\overline{CS}$ should be LOW t_{OE} before $\overline{OE}$ is brought LOW.

When EOC goes HIGH, the conversion is completed and the output data may be read. The output is read in two steps as a 16-bit word, with the high byte read first, followed by the low byte. High Byte Enable ($\overline{HBE}$) controls the output sequence. The 14-bit result is left justified within the 16-bit field.

In unipolar mode (BIPOFF tied to AGND), the output coding is straight binary. In bipolar mode (BIPOFF tied to REF_{OUT}), output coding is twos-complement binary.

POWER-UP

The AD679 typically requires 10 µs after power-up to reset internal logic.

CONVERSION STATUS TRUTH TABLE

	INPUTS			OUTPUT	
	SYNC	$\overline{CS}$	$\overline{EOCEN}$	EOC	STATUS
Synchronous Mode	1	0	0	0	Converting
	1	0	0	1	Not Converting
	1	1	X	High Z	Either
	1	X	1	High Z	Either

Data coding is binary for Unipolar Mode and 2s Complement Binary for Bipolar Mode.

INPUT CONNECTIONS AND CALIBRATION

The high (10 MΩ) input impedance of the AD679 eases the task of interfacing to high source impedances or multiplexer channel-to-channel mismatches of up to 300 Ω. The 10 V p–p full scale input range accepts the majority of signal voltages without the need for voltage divider networks which could deteriorate the accuracy of the ADC.

The AD679 is factory trimmed to minimize offset, gain and linearity errors. In unipolar mode, the only external component that is required is a 50 Ω ±1% resistor. Two resistors are required in bipolar mode. If offset and gain are not critical (as in some ac applications), even these components can be eliminated.

In some applications, offset and gain errors need to be trimmed out completely. The following sections describe the correct procedure for these various situations.

BIPOLAR RANGE INPUTS

The connections for the bipolar mode are shown in Figure 5. In this mode, data output coding will be twos complement binary. This circuit will allow approximately ±25 mV of offset trim range (±40 LSB) and ±0.5% of gain trim range (±80 LSB).

Either or both of the trim pots can be replaced with 50 Ω ±1% fixed resistors if the AD679 accuracy limits are sufficient for application. If the pins are shorted together, the additional offset and gain errors will be approximately 80 LSB.

To trim bipolar zero to its nominal value, apply a signal 1/2 LSB below midrange (−0.305 mV for a ±5 V range) and adjust R1 until the major carry transition is located (11 1111 1111 1111 to 00 0000 0000 0000). To trim the gain, apply a signal 1 1/2 LSB below full scale (+4.9991 V for a ±5 V range) and adjust R2 to give the last positive transition (01 1111 1111 1110 to 01 1111 1111 1111). These trims are interactive so several iterations may be necessary for convergence.

A single pass calibration can be done by substituting a bipolar offset trim (error at minus full scale) for the bipolar zero trim (error at midscale), using the same circuit. First, apply a signal 1/2 LSB above minus full scale (−4.9997 V for a ±5 V range) and adjust R1 until the minus full scale transition is located (10 0000 0000 0000 to 10 000 000 0001). Then perform the gain error trim as outlined above.

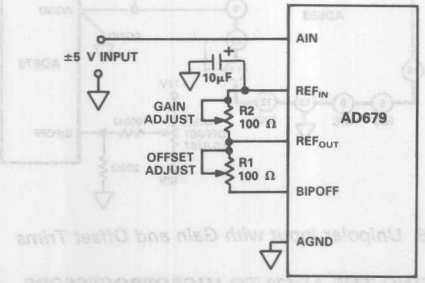

Figure 5. Bipolar Input Connections with Gain and Offset Trims

UNIPOLAR RANGE INPUTS

Offset and gain errors can be trimmed out by using the configuration shown in Figure 6. This circuit allows approximately ±25 mV of offset trim range (±40 LSB) and ±0.5% of gain trim range (±80 LSB).

The nominal offset is 1/2 LSB so that the analog range that corresponds to each code will be centered in the middle of that code (halfway between the transitions to the codes above and below it). Thus the first transition (from 00 0000 0000 0000 to 00 0000 0000 0001) should nominally occur for an input level of +1/2 LSB (0.305 mV above ground for a 10 V range). To trim unipolar zero to this nominal value, apply a 0.305 mV signal to AIN and adjust R1 until the first transition is located.

The gain trim is done by adjusting R2. If the nominal value is required, apply a signal 1 1/2 LSB below full scale (9.9997 V for a 10 V range) and adjust R2 until the last transition is located (11 1111 1111 1110 to 11 1111 1111 1111).

If offset adjustment is not required, BIPOFF should be connected directly to AGND. If gain adjustment is not required, R2 should be replaced with a fixed 50 Ω ±1% metal film resistor. If REF_{OUT} is connected directly to REF_{IN}, the additional gain error will be approximately 1%.

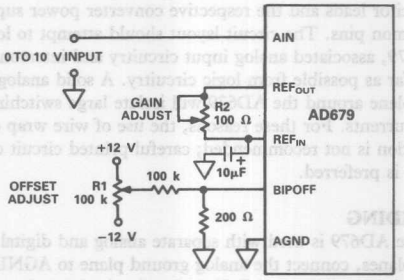

Figure 6. Unipolar Input Connections with Gain and Offset Trims

REFERENCE DECOUPLING

It is recommended that a 10 μF tantalum capacitor be connected between REF_{IN} (Pin 9) and ground. This has the effect of improving the S/N+D ratio through filtering possible broadband noise contributions from the voltage reference.

BOARD LAYOUT

Designing with high resolution data converters requires careful attention to board layout. Trace impedance is a significant issue. A 1.22 mA current through a 0.5 Ω trace will develop a voltage drop of 0.6 mV, which is 1 LSB at the 14 bit level for a 10 V full scale span. In addition to ground drops, inductive and capacitive coupling need to be considered, especially when high accuracy analog signals share the same board with digital signals. Finally, power supplies need to be decoupled in order to filter out ac noise.

Analog and digital signals should not share a common path. Each signal should have an appropriate analog or digital return routed close to it. Using this approach, signal loops enclose a small area, minimizing the inductive coupling of noise. Wide PC tracks, large gauge wire, and ground planes are highly recommended to provide low impedance signal paths. Separate analog

connection point to minimize ground loops. Analog signals should be routed as far as possible from digital signals and should cross them at right angles.

The AD679 incorporates several features to help the user's layout. Analog pins (V_{EE}, AIN, AGND, REF_{OUT}, REF_{IN}, BIPOFF, V_{CC}) are adjacent to help isolate analog from digital signals. In addition, the 10 MΩ input impedance of AIN minimizes input trace impedance errors. Finally, ground currents have been minimized by careful circuit architecture. Current through AGND is 200 μA, with no code dependent variation. The current through DGND is dominated by the return current for DB7–DB0 and EOC.

SUPPLY DECOUPLING

The AD679 power supplies should be well filtered, well regulated, and free from high frequency noise. Switching power supplies are not recommended due to their tendency to generate spikes which can induce noise in the analog system.

Decoupling capacitors should be used in very close layout proximity between all power supply pins and analog ground. A 10 μF tantalum capacitor in parallel with a 0.1 μF ceramic capacitor provides adequate decoupling.

An effort should be made to minimize the trace length between the capacitor leads and the respective converter power supply and common pins. The circuit layout should attempt to locate the AD679, associated analog input circuitry and interconnections as far as possible from logic circuitry. A solid analog ground plane around the AD679 will isolate large switching ground currents. For these reasons, the use of wire wrap circuit construction is not recommended; careful printed circuit construction is preferred.

GROUNDING

If a single AD679 is used with separate analog and digital ground planes, connect the analog ground plane to AGND and the digital ground plane to DGND keeping lead lengths as short as possible. Then connect AGND and DGND together at the AD679. If multiple AD679s are used or the AD679 shares analog supplies with other components, connect the analog and digital returns together once at the power supplies rather than at each chip. This prevents large ground loops which inductively couple noise and allow digital currents to flow through the analog system.

USE OF EXTERNAL VOLTAGE REFERENCE

The AD679 features an on-chip voltage reference. For improved gain accuracy over temperature, a high performance external voltage reference may be used in place of the on-chip reference.

The AD586 and AD588 are popular references appropriate for use with high resolution converters. The AD586 is a low cost reference which utilizes a buried Zener architecture to provide low noise and drift. The AD588 is a higher performance reference which uses a proprietary ion-implanted buried Zener diode in conjunction with laser-trimmed thin-film resistors for low offset and low drift.

Figure 7 shows the use of the AD586 with the AD679 in a bipolar input mode. Over the 0 to +70°C range, the AD586 L-grade exhibits less than a 2.25 mV output change from its initial value at 25°C. REF_{IN} (Pin 9) scales its input by a factor of two; thus, AD679, this results in a total gain drift of 0.09% FSR, which is an improvement over the on-chip reference performance of 0.11% FSR. A noise-reduction capacitor, C_N, has been shown. This capacitor reduces the broadband noise of the AD586 output, thereby optimizing the overall ac and dc performance of the AD679.

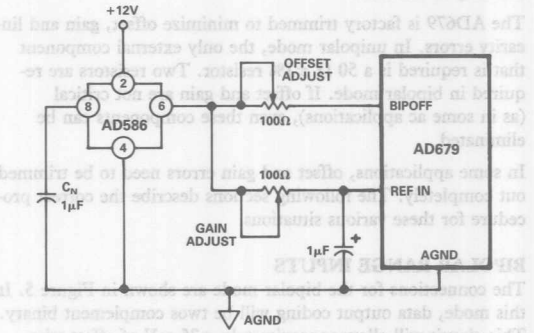

Figure 7. Bipolar Input with Gain and Offset Trims

Figure 8 shows the AD679 in unipolar input mode with the AD588 reference. The AD588 output is accurate to 0.65 mV from its value at 25°C over the 0 to 70°C range. This results in a 0.06% FSR total gain drift for the AD679, which is a substantial improvement over the on-chip reference performance of 0.11% FSR. A noise-reduction network on Pins 4, 6 and 7 has been shown. The 1 μF capacitors form low pass filters with the internal resistance of the AD588 Zener and amplifier cells and external resistance. This reduces the high frequency (to 1 MHz) noise of the AD588, providing optimum ac and dc performance of the AD679.

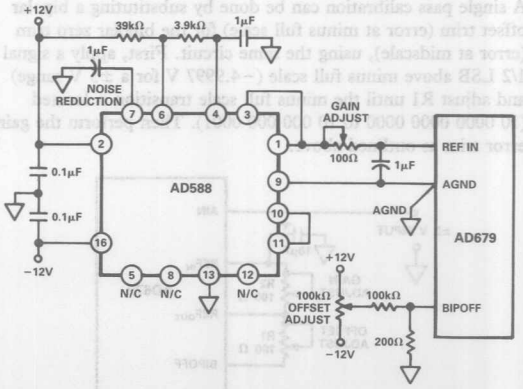

Figure 8. Unipolar Input with Gain and Offset Trims

INTERFACING THE AD679 TO MICROPROCESSORS

The I/O capabilities of the AD679 allow direct interfacing to general purpose and DSP microprocessor buses. The asynchronous conversion control feature allows complete flexibility and control with minimal external hardware.

The following examples illustrate typical AD679 interface configurations.

AD679 to TMS320C25

In Figure 9 the AD679 is mapped into the TMS320C25 I/O space. AD679 conversions are initiated by issuing an OUT instruction to Port 1. EOC status and the conversion result are read in with an IN instruction to Port 1. A single wait state is inserted by generating the processor READY input from $\overline{IS}$, Port 1 and $\overline{MSC}$. Address line A0 provides $\overline{HBE}$ decoding to select between the high and low bytes of data. This configuration supports processor clock speeds of 20 MHz and is capable of supporting processor clock speeds of 40 MHz if a NOP instruction follows each AD679 read instruction.

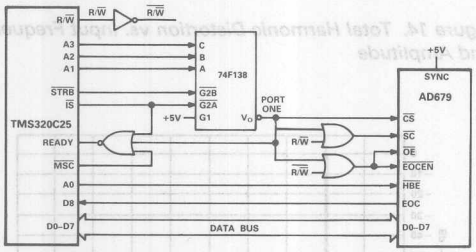

Figure 9. AD679 to TMS320C25 Interface

AD679 to 80186

Figure 10 shows the AD679 interfaced to the 80186 microprocessor. This interface allows the 80186's built-in DMA controller to transfer the AD679 output into a RAM based FIFO buffer of any length, with no microprocessor intervention.

In this application the AD679 is configured in the asynchronous mode, which allows conversions to be initiated by an external trigger source independent of the microprocessor clock. After each conversion, the AD679 EOC signal generates a DMA request to Channel 1 (DRQ1). The subsequent DMA READ sequences the high and low byte AD679 data and resets the interrupt latch. The system designer must assign a sufficient priority to the DMA channel to ensure that the DMA request will be serviced before the completion of the next conversion. This configuration can be used with 6 MHz and 8 MHz 80186 processors.

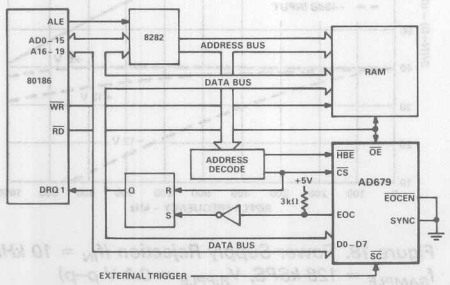

Figure 10. AD679 to 80186 DMA Interface

AD679 to Analog Devices ADSP-2101

Figure 11 demonstrates the AD679 interfaced to an ADSP-2101. With a clock frequency of 12.5 MHz, and instruction execution in one 80 ns cycle, the digital signal processor supports the AD679 interface with one wait state.

The converter is configured to run asynchronously using a sampling clock. The EOC output of the AD679 gets asserted at the end of each conversion and causes an interrupt. Upon interrupt, the ADSP-2101 immediately asserts its FO pin LOW. In the following cycle, the processor starts a data memory read by providing an address on the DMA bus. The decoded address generates $\overline{OE}$ for the converter, and the high byte of the conversion result is read over the data bus. The read operation is extended with one wait state and thus started and completed within two processor cycles (160 ns). Next, the ADSP-2101 asserts its FO HIGH. This allows the processor to start reading the lower byte of data. This read operation executes in a similar manner to the first and is completed during the next 160 ns.

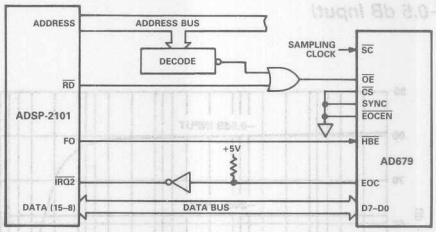

Figure 11. AD679 to ADSP-2101 Interface

AD679 to Analog Devices ADSP-2100A

Figure 12 demonstrates the AD679 interfaced to an ADSP-2100A. With a clock frequency of 12.5 MHz, and instruction execution in one 80 ns cycle, the digital signal processor will support the AD679 data memory interface with three hardware wait states.

The converter is configured to run asynchronously using a sampling clock. The EOC output of the AD679 gets asserted at the end of each conversion and causes an interrupt. Upon interrupt, the ADSP-2100A immediately executes a data memory write instruction which asserts $\overline{HBE}$. In the following cycle, the processor starts a data memory read (high byte read) by providing an address on the DMA bus. The decoded address generates $\overline{OE}$ for the converter. $\overline{OE}$, together with logic and latch, is used to force the ADSP-2100A into a one cycle wait state by generating DMACK. The read operation is thus started and completed within two processor cycles (160 ns). $\overline{HBE}$ is released during "high byte read." This allows the processor to read the lower byte of data as soon as "high byte read" is complete. The low byte read operation executes in a similar manner to the first and is completed during the next 160 ns.

PRODUCT DESCRIPTION

The AD770 is an 8-bit analog-to-digital converter that is designed for high-speed digitization of wide-bandwidth signals. It uses an advanced VLSI bipolar process and a proprietary design to achieve a combination of sampling rate and signal bandwidth previously unavailable in flash ADCs.

The AD770 incorporates 257 high speed comparators that are optimized for low input capacitance and wide bandwidth, unaffected by temperature or signal amplitude. The multistage comparator design reduces the probability of errors due to metastable states or insufficient gain.

The decoding logic further reduces errors by using a two-stage error-correcting architecture to virtually eliminate "sparkle codes." Inputs and outputs are ECL compatible. Output format controls allow stacking of two devices for 9-bit resolution. Overflow and underflow output signals are provided.

The AD770 can operate with unipolar and bipolar signal ranges up to 4V p-p. End-point reference Force and Sense connections are provided to preserve high accuracy and minimize temperature drift. Midpoint and quarter-point reference taps are also provided to allow linearity or transfer function corrections.

The AD770 is available in three grades. The JD and KD grades are specified for operation over the 0 to +70°C temperature range, while the SD grade is specified for the −55°C to +125°C temperature range. All grades are packaged in a 40-pin ceramic DIP. Other package options are available on request; please contact the factory.

PRODUCT HIGHLIGHTS

1. **Performance:** The AD770 is specified for operation at 200 MSPS. Full power bandwidth is 250MHz; small signal bandwidth is 400MHz.
2. **Ease of Use:** The AD770 input has a typical capacitance of 19pF, simplifying input buffering requirements. Bipolar and unipolar input signals can be converted without offsetting. Differential or single-ended clock inputs can be accommodated by pin-strapping.
3. **Features:** Taps are provided at mid- and quarter-scale points of the reference ladder to permit linearity trimming or piecewise-linear transfer function modification. Overflow and underflow signals are also provided. These can be wire-or'd to provide an indication that the input signal has exceeded the range of the converter.

EVALUATION BOARD

The ADEB770 Evaluation Board allows the designer to easily evaluate the performance of the AD770. The ADEB770 includes a pin-socketed AD770, an input signal buffer and an adjustable reference generator. The input buffer can be bypassed for maximum versatility.

On the output side, latched and buffered digital data is available at the output connector along with an output clock. Decimation hardware allows output data to be undersampled by factors of 16 through 2, allowing the user to interface the board to commonly available logic analyzers.

A reconstructed analog output is also provided by an on-board D/A converter.

DEFINITION OF SPECIFICATIONS

Linearity Error
Linearity Error is the deviation of the transfer function from a reference line. For the AD770, the linearity error is measured from the center of each code to the best-fit straight line.

Differential Linearity
In an ideal ADC, the code transitions are exactly 1LSB apart. The Differential Linearity is the deviation of the transition spacing from the ideal value. A Differential Linearity spec of less than 1LSB signifies that there are no missing output codes over the entire input range.

Absolute Accuracy
The Absolute Accuracy is the deviation of the center-point of each code from a straight line drawn between the reference sense points (REFTS, REFBS).

Force-Sense Offset
The Force-Sense Offset is the difference between the force and sense pin voltages divided by the input range. This offset will cause a corresponding offset error if the full-scale range is defined w.r.t. the reference force lines rather than with respect to the reference sense lines.

Aperture Delay
The delay between the falling edge of CLK and the time at which AIN is sampled.

Aperture Jitter
The sample-to-sample variation in aperture delay.

Pipeline Delay
The delay from the falling edge of CLK that samples the input to the rising edge of CLK that outputs the corresponding digital code.

Output Delay
The delay between the rising edge of CLK and the time when the output bits reach the logic threshold value for bits D0 to D7 and OVR.

Output Skew
The bit-to-bit variation in output delay for bits D0 to D7 and OVR.

Full-Power Bandwidth
The input frequency at which the amplitude of the reconstructed output signal is reduced by 3dB for a full-scale input.

Total Harmonic Distortion (THD)
The rms sum of the first six harmonic components divided by the output signal amplitude. For frequencies above the Nyquist frequency, the aliased components are used.

Signal-to-Noise Ratio (SNR)
The ratio of the signal amplitude to the rms sum of all other spectral components, including harmonics but excluding dc. SNR is expressed in dB and in Effective Number Of Bits (ENOB). These two notations are related by the following formula for full-scale inputs:

$$ENOB = (SNR - 1.8)/6.02$$

(For REFTS = +1.000V, REFBS = −1.000V)

The user is advised to provide separate, low impedance analog and digital ground planes and tie them together at one place on the board, preferably at, or as near to, the ADC as possible.

The dominant consideration in the selection of bypass capacitors for the AD770 is minimization of series resistance and inductance. Ceramic and film-type capacitors generally feature lower series inductance than tantalum or electrolytic types. The capacitors should be installed on the board with the shortest possible lead lengths. Chip capacitors are optimal in this respect. As shown in Figure 18, the analog ground plane provides bypassing for the analog power supplies (AV_{CC}, AV_{EE}) as well as for the reference top, bottom, mid and quarter voltages. The digital ground plane should be used to bypass the digital supplies (DV_{CC}, DV_{EE}).

To prevent output ringing, a ferrite bead in series with DGND Pins 36 and 37 is recommended. Output lines should be single fanout, properly terminated 100Ω striplines for best results.

DRIVING THE AD770

The AD770 can be driven directly from most signal sources. The termination of the signal source, however, will affect the input bandwidth. Two possibilities are shown in Figure 16.

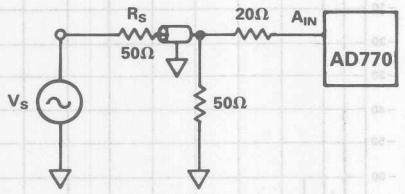

Figure 16a. 50Ω Shunt Termination

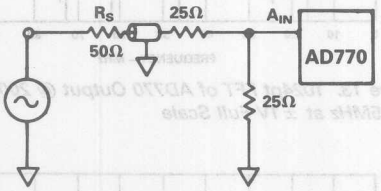

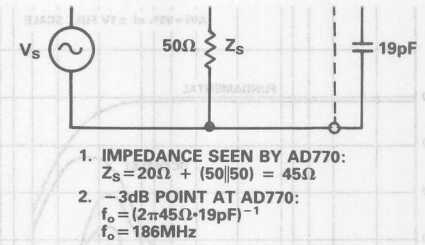

Figure 16b. 50Ω Termination (−6dB) Employing 25Ω Series and 25Ω Shunt Resistors

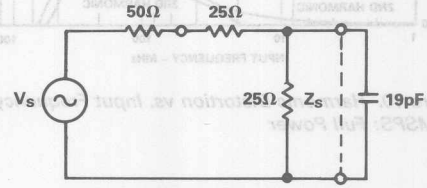

Both terminations result in 50Ω to ground; however the network of Figure 16b provides a lower impedance to the AD770 over frequency as well as a higher −3dB point at the device. The trade-off is that Figure 16b attenuates the signal source by a factor of two (−6dB). These effects may be illustrated by modeling the input to the AD770 as a 19pF capacitor and analyzing the two termination networks as shown in Figure 17.

The −6dB network requires an input signal with twice the amplitude of the simple 50Ω shunt termination, but the benefits can be easily justified. The termination impedance reaches a high frequency value of 25Ω, versus 14Ω for the standard termination network. Another advantage is that the half-power bandwidth is more than twice that of the standard 50Ω shunt network.

1. IMPEDANCE SEEN BY AD770:
   $Z_S = 20\Omega + (50 \| 50) = 45\Omega$
2. −3dB POINT AT AD770:
   $f_o = (2\pi 45\Omega \cdot 19pF)^{-1}$
   $f_o = 186MHz$

Figure 17a. Network for 50Ω Shunt Termination

1. IMPEDANCE SEEN BY AD770:
   $Z_S = 25\Omega \| 25\Omega + 50\Omega) = 19\Omega$
2. −3dB POINT AT AD770:
   $f_o = (2\pi 19\Omega \cdot 19pF)^{-1}$
   $f_o = 441MHz$

Figure 17b. Network for 25Ω Series and 25Ω Shunt Termination.

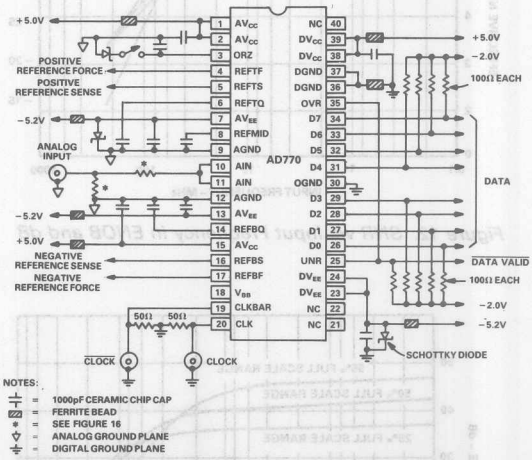

Figure 18. AD770 Application Example

LATCHING THE OUTPUT DATA

A simplified AD770 timing diagram is illustrated in Figure 19. The input signal is sampled on the falling edge of CLK. The output data for that sample is delayed by the Pipeline Delay plus the Output Delay. The Pipeline Delay is two CLK low periods and one CLK high period, and thus depends on the conversion rate and the clock duty cycle. Output Delay is measured from the second CLK rising edge after the falling edge which samples the analog input signal. Output Delay is not dependent on the conversion rate.

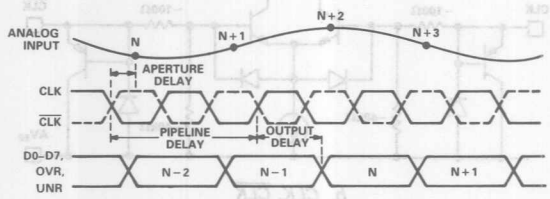

Figure 19. AD770 Timing Diagram

Output Delay varies from unit to unit due to manufacturing process variations. This factor, and the timing requirements of the external latch, must be considered when designing the output clock circuit.

Figure 20 shows a more detailed timing diagram that illustrates the effect of Output Delay variations and external latch timing requirements. Data bit transitions are shown for units at the extreme limits of Output Delay (T_D). For a unit with $T_D = T_{Dmin}$, the data bits will begin to slew after a delay of T_{Dmin}, and all bits will have settled after a further delay of T_{SK} (Output Skew). The data will then be stable until the next output data transition.

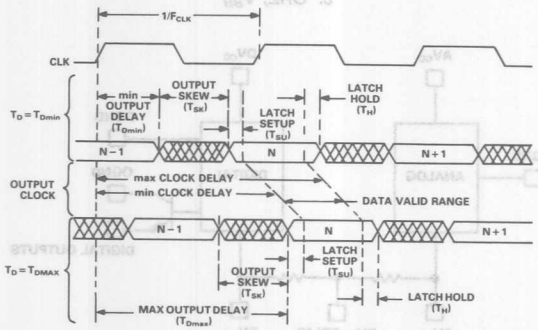

Figure 20. Detailed Timing Diagram Showing Output Delay Variation

However, the Setup and Hold times (T_{SU} and T_H) of the external latch must be subtracted to obtain the interval during which the external latch can be clocked (Data Valid Range). Thus:

$$\text{Data Valid Range} = 1/F_{CLK} - T_{SK} - T_{SU} - T_{TH}$$

The clock circuit will require a maximum delay that can also be easily derived:

$$\text{Max Clock Delay (for } T_D = T_{Dmin}) = 1/F_{CLK} + T_{Dmin} - T_H$$

For a unit with $T_D = T_{Dmax}$, the clock delay will be determined by the Maximum Output Delay (T_{Dmax}):

$$\text{Min Clock Delay (for } T_D = T_{Dmax}) = T_{Dmax} + T_{SU}$$

If the Maximum Clock Delay for $T_D = T_{Dmin}$ is greater than the Minimum Clock Delay for $T_D = T_{Dmax}$, a fixed clock delay set between these two values can be used to latch the output of the AD770.

$$T_{Dmax} + T_{SU} < \text{Fixed Clock Delay} < 1/F_{CLK} + T_{Dmin} - T_H$$

For example, a 120 MSPS system using 100K ECL logic would have the following conditions:

$T_{Dmax} = 6.0\text{ns}$
$T_{SU} = 0.7\text{ns}$
$F_{CLK} = 120\text{MHz}$
$T_{Dmin} = 2.0\text{ns}$
$T_H = 0.7\text{ns}$

$$\text{Max Clock Delay (for } T_D = T_{Dmin}) = 1/F_{CLK} + T_{Dmin} - T_H = 9.6\text{ns}$$

$$\text{Min Clock Delay (for } T_D = T_{Dmax}) = T_{Dmax} + T_{SU} = 6.7\text{ns}$$

A fixed clock delay could thus be used, with the following limits:

$$6.7\text{ns} < \text{Clock Delay} < 9.6\text{ns}$$

As the sample rate increases, the range of fixed clock delays becomes narrower. At 150 MSPS, using the same logic family, the range becomes:

$$6.7\text{ns} < \text{Clock Delay} < 8.0\text{ns}$$

At 200 MSPS, a fixed delay can no longer be used, since

Max Clock Delay (for $T_D = T_{Dmin}$) = 6.3ns
Min Clock Delay (for $T_D = T_{Dmax}$) = 6.7ns

The user should calculate whether a fixed delay can be used in the system. If a fixed delay cannot be used, a variable delay line is needed.

VARIABLE DELAY LINE

Continuing with the example above, we can determine the span of delays that is needed.

At 200 MSPS:

Max Clock Delay (for $T_D = T_{Dmin}$) = 6.3ns
Min Clock Delay (for $T_D = T_{Dmax}$) = 6.7ns
Data Valid Range (for each device) < 1.25ns.

The clock delay should have an adjustment range between (6.3 − 1.25/2) = 5.7ns and (6.7 + 1.25/2) = 7.3ns to center the clock edge in the middle of the Data Valid range for all devices.

If a variable delay line is used, some means must be provided to verify that the delay is correctly set for each device. This can be done by providing a test signal synchronized to the system timing and adjusting the delay to the centerpoint of the range that gives a stable output.

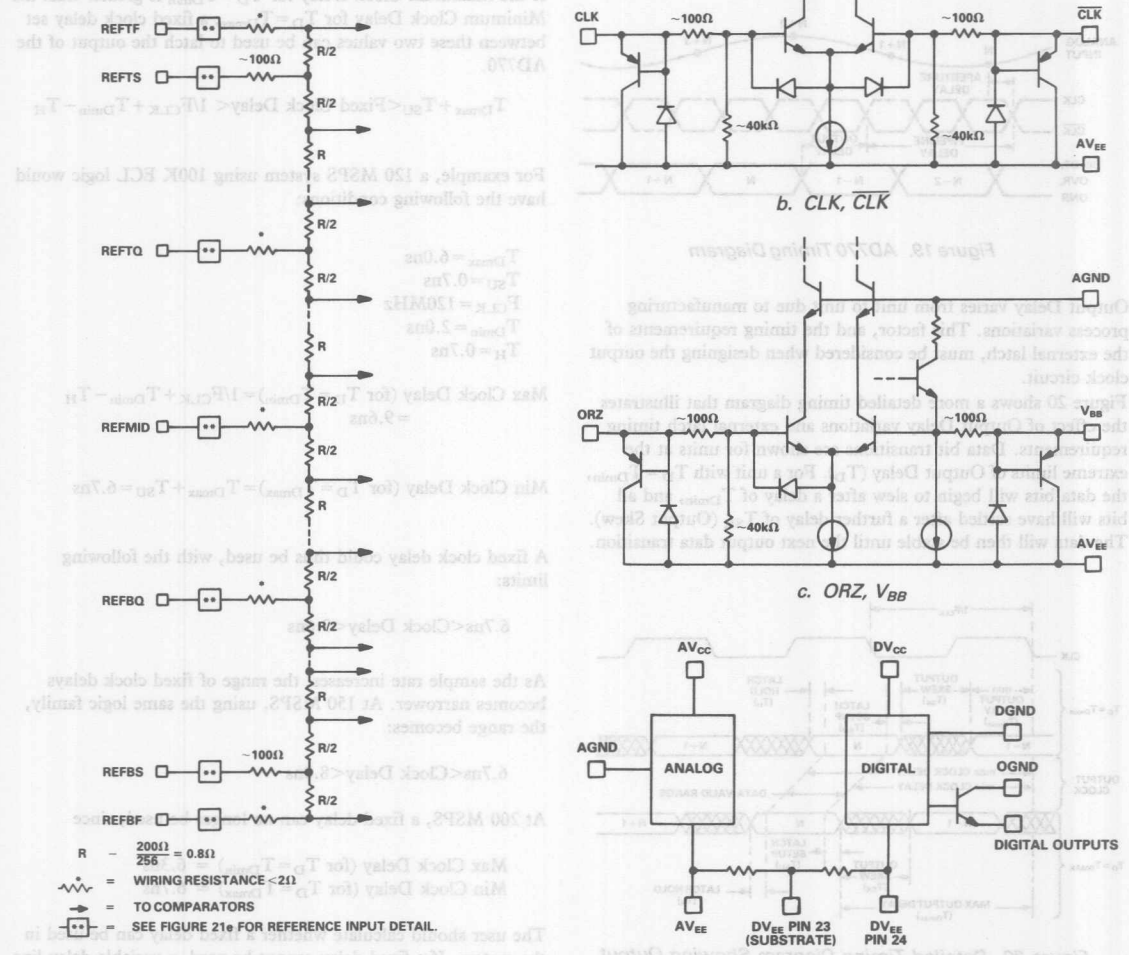

Figure 21. Equivalent Circuits

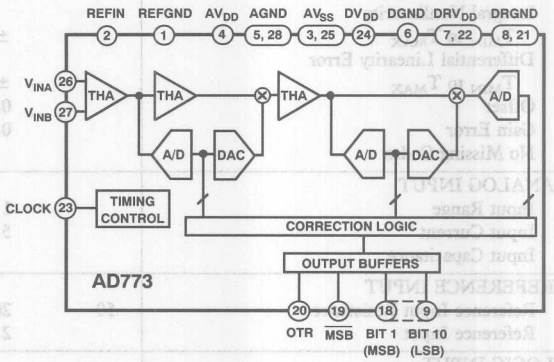
10-Bit 18 MSPS Monolithic A/D Converter



AD773

2

FEATURES

- Monolithic 10-Bit 18 MSPS A/D Converter
- Low Power Dissipation: 1.2 W
- Signal-to-Noise Plus Distortion Ratio
  - f_{IN} = 1 MHz: 55 dB
  - f_{IN} = 8 MHz: 52 dB
- Guaranteed No Missing Codes
- On-Chip Track-and-Hold Amplifier
- 100 MHz Full Power Bandwidth
- High Impedance Reference Input
- Out of Range Output
- Twos Complement and Binary Output Data
- Available in Commercial and Military Temperature Ranges

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD773 is a monolithic 10-bit, 18 MSPS analog-to-digital converter incorporating an on-board, high performance track-and-hold amplifier (THA). The AD773 converts video bandwidth signals without the use of an external THA. The AD773 implements a multistage differential pipelined architecture with output error correction logic. The AD773 offers accurate performance and guarantees no missing codes over the full operating temperature range.

Output data is presented in binary and twos complement format. An out of range (OTR) signal indicates the analog input voltage is beyond the specified input range. OTR can be decoded with the MSB/$\overline{\text{MSB}}$ pins to signal an underflow or overflow condition. The high impedance reference input allows multiple AD773s to be driven in parallel from a single reference.

The combined dc precision and dynamic performance of the AD773 is useful in a variety of applications. Typical applications include: video enhancement, HDTV, ghost cancellation, ultrasound imaging, radar and high speed data acquisition.

The AD773 was designed using Analog Devices' ABCMOS-1 process which utilizes high speed bipolar and 2-micron CMOS transistors on a single chip. High speed, precision analog circuits are now combined with high density logic circuits. Laser trimmed thin film resistors are used to optimize accuracy and temperature stability.

The AD773 is packaged in a 28-pin ceramic DIP and is available in commercial (0°C to +70°C) and military (−55°C to +125°C) grades.

PRODUCT HIGHLIGHTS

1. On-board THA
   The high impedance differential input THA eliminates the need for external buffering or sample and hold amplifiers. The THA offers the choice of differential or single-ended inputs. Input current is typically 5 μA.
2. High Impedance Reference Input
   The high impedance reference input (200 kΩ) allows direct connection with standard +2.5 V references, such as the AD680, AD580 and REF43.
3. Output Data Flexibility
   Output data is available in bipolar offset and bipolar twos complement binary format.
4. Out of Range (OTR)
   The OTR output bit indicates when the input signal is beyond the AD773's input range.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

PIN CONFIGURATION

PIN DESCRIPTION

Symbol	Pin No.	Type	Name and Function
AGND	5, 28	P	Analog Ground.
AV_{DD}	4	P	+5 V Analog Supply.
AV_{SS}	3, 25	P	−5 V Analog Supply.
BIT 1 (MSB)	18	DO	Most Significant Bit.
BIT 2–BIT 9	17–10	DO	Data Bit 2 through Data Bit 9.
BIT 10 (LSB)	9	DO	Least Significant Bit.
CLK	23	DI	Clock Input. The AD773 will initiate a conversion on the falling edge of the clock input. See the Timing Diagram for details.
DV_{DD}	24	P	+5 V Digital Supply.
DRV_{DD}	7, 22	P	+5 V Digital Supply for the output drivers.
DGND	6	P	Digital Ground.
DRGND	8, 21	P	Digital Ground for the output drivers.
$\overline{MSB}$	19	DO	Inverted Most Significant Bit. Provides twos complement output data format.
OTR	20	DO	Out of Range is Active HIGH on the leading edge of Code 0 or the trailing edge of Code 1023. See Output Data Format Table II.
REF GND	1	AI	REF GND is connected to the ground of the external reference.
REF IN	2	AI	REF IN is the external 2.5 V reference input, taken with respect to REF GND.
V_{INA}	26	AI	(+) Analog input signal to the differential input THA.
V_{INB}	27	AI	(−) Analog input signal to the differential input THA.

Type: AI = Analog Input; DI = Digital Input; DO = Digital Output; P = Power.

INTEGRAL NONLINEARITY (INL)
Linearity error refers to the deviation of each individual code from a line drawn from "zero" through "full scale." The point used as "zero" occurs 1/2 LSB before the first code transition. "Full scale" is defined as a level 1 1/2 LSB beyond the last code transition. The deviation is measured from the center of each particular code to the true straight line.

DIFFERENTIAL LINEARITY ERROR (DNL, NO MISSING CODES)
An ideal ADC exhibits code transitions that are exactly 1 LSB apart. DNL is the deviation from this ideal value.

OFFSET
The first transition should occur at a level 1/2 LSB above "zero." Offset is defined as the deviation of the actual first code transition from that point.

GAIN ERROR
The last code transition should occur for an analog value 1 1/2 LSB below the nominal full scale. The gain error is the deviation of the actual level at the last transition from the ideal level.

POWER SUPPLY REJECTION
One of the effects of power supply variation on the performance of the device will be a change in gain error. The specification shows the maximum gain error deviation as the supplies are varied from their nominal values to their specified limits.

SIGNAL-TO-NOISE PLUS DISTORTION (S/N+D) RATIO
S/N+D is the ratio of the rms value of the measured input signal to the rms sum of all other spectral components including harmonics but excluding dc. The value for S/N+D is expressed in decibels.

EFFECTIVE NUMBER OF BITS (ENOB)
ENOB is calculated from the following expression:

S/N+D = 6.02N + 1.76, where N is equal to the effective number of bits.

TOTAL HARMONIC DISTORTION (THD)
THD is the ratio of the rms sum of the first six harmonic components to the rms value of the measured input signal and is expressed as a percentage or in decibels.

SPURIOUS FREE DYNAMIC RANGE
The peak spurious or peak harmonic component is the largest spectral component excluding the input signal and dc. This value is expressed in decibels relative to the rms value of a full-scale input signal.

INTERMODULATION DISTORTION (IMD)
With inputs consisting of sine waves at two frequencies, fa and fb, any device with nonlinearities will create distortion products, of order (m+n), at sum and difference frequencies of mfa±nfb, where m, n = 0, 1, 2, 3 . . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are (fa+fb) and (fa−fb) and the third order terms are (2fa+fb), (2fa−fb), (fa+2fb) and (fa−2fb). The IMD products are expressed as the decibel ratio of the rms sum of the measured input signals to the rms sum of the distortion terms. The two signals are of equal amplitude and the peak value of their sums is −0.5 dB from full scale. The IMD products are normalized to a 0 dB input signal.

DIFFERENTIAL GAIN
The percentage difference between the output amplitudes of a small high frequency sine wave at two stated levels of a low frequency signal on which it is superimposed.

DIFFERENTIAL PHASE
The difference in the output phase of a small high frequency sine wave at two stated levels of a low frequency signal on which it is superimposed.

TRANSIENT RESPONSE
The time required for the AD773 to achieve its rated accuracy after a full-scale step function is applied to its input.

OVERVOLTAGE RECOVERY TIME
The time required for the ADC to recover to full accuracy after an analog input signal 150% of full scale is reduced to 50% of the full-scale value.

APERTURE DELAY
The difference between the switch delay and the analog delay of the THA. This effective delay represents the point in time, relative to the rising edge of the CLOCK input, that the analog input is sampled.

APERTURE JITTER
The variations in aperture delay for successive samples.

PIPELINE DELAY (LATENCY)
The number of clock cycles between conversion initiation and the associated output data being made available. New output data is provided every clock cycle.

FULL POWER BANDWIDTH
The input frequency at which the amplitude of the reconstructed fundamental is reduced by 3 dB for a full-scale input.

Theory of Operation

The AD773 uses a pipelined multistage architecture with a differential input, fast settling track-and-hold amplifier (THA). Traditionally, high speed ADCs have used parallel, or flash architectures. When compared to flash converters, multistage architectures reduce the power dissipation and die size by reducing the number of comparators. For example, the AD773 uses 48 comparators compared to 1023 comparators for a 10-bit flash architecture.

The AD773's main signal path transmits differential current mode signals. Low impedance current summing techniques are employed, increasing speed by reducing sensitivity to parasitic capacitances. Pipelining allows the stages to operate concurrently and maximizes system throughput.

The input THA is followed by three 4-bit conversion stages. At any given time, the first stage operates on the most recent sample, while the second stage operates on a signal dependent on the previous sample. This process continues throughout all three stages. The twelve digital bits provided by the three 4-bit stages are combined in the correction logic to produce a 10-bit representation of the sampled analog input.

Pipeline delay, or latency, is four clock cycles. New output data is provided every clock cycle and is provided in both binary and twos complement format. The AD773 will flag an out-of-range condition when the analog input exceeds the specified analog input range.

Applying the AD773

DRIVING THE AD773 INPUT

The AD773 may be driven in a single-ended or differential fashion. V_{INA} is the positive input, and V_{INB} is the negative input. In the signle-ended configuration either V_{INA} or V_{INB} is connected to Analog Ground (AGND) while the other input is driven with a full-scale input of ±500 mV p–p. An inverted mode of operation can be achieved by simply interchanging the input connections.

Both inputs of the AD773, V_{INA} and V_{INB}, are high impedance and do not need to be driven by a low impedance source. Note, however, that as the source impedance increases, the input node becomes more susceptible to noise. The increased noise at the input will degrade performance. A 10 pF capacitor across V_{INA} and V_{INB} as shown in Figure 14 is recommended to bypass high frequency noise.

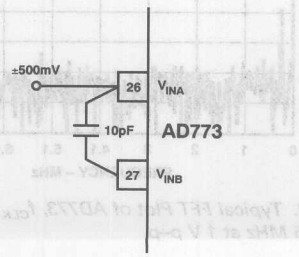

Figure 14. AD773 Single-Ended Input Connection

INPUT CONDITIONING

In some cases, it may be appropriate to buffer the input source, add dc offset, or otherwise condition the input signal of the AD773. Choosing an appropriate op amp will vary with system requirements and the desired level of performance. Some suggested op amps are the AD9617, AD842, and AD827.

Figure 15 shows a typical application where a unipolar signal is level shifted to the bipolar input range of the AD773. Note that the reference used with the AD773 can also provide a noise-free voltage source to generate the dc offset.

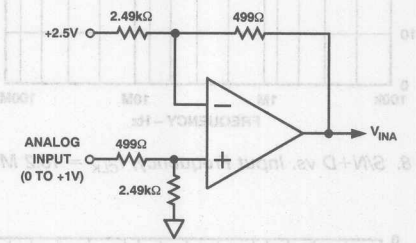

Figure 15. Unipolar to Bipolar Input Connection

DIFFERENTIAL INPUT CONNECTIONS

Operating the AD773 with fully differential inputs offers the advantage of rejecting common-mode signals present on both V_{INA} and V_{INB}. The full-scale input range of V_{INA} and V_{INB} when driven differentially is ±250 mV p–p as shown in Table I.

Table I. AD773's Maximum Differential Input Voltage

V_{INA}	V_{INB}	V_{INA}–V_{INB}
+250 mV	−250 mV	+500 mV
−250 mV	+250 mV	−500 mV

In some applications it may be desirable to convert a single-ended signal to a differential signal before being applied to the AD773. Figure 16 shows a single-ended to differential video line driver capable of driving doubly terminated cables.

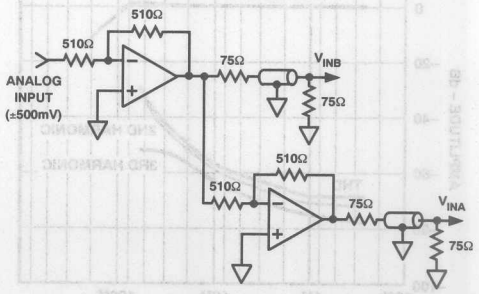

Figure 16. Single-Ended to Differential Connection

REFERENCE INPUT

The AD773's high impedance reference input allows direct connection with standard voltage references. Unlike the resistor ladder requirements of a flash converter the AD773's single pin, high impedance input can be driven from one low cost, low power reference. The high impedance input allows multiple AD773's to be driven from one reference thus minimizing drift errors.

Figure 17 shows the AD773 connected to the AD680. The AD680 is a single supply, low power, low cost 2.5 V reference with performance specifications ideally suited for the AD773. The low pass filter minimizes the AD680's wideband noise. Other recommended 2.5 V references are the AD580 and REF43.

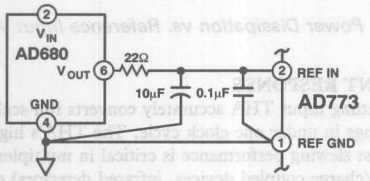

Figure 17. Recommended AD773 to AD680 Connection

CLOCK INPUT

The AD773's pipelined architecture operates on both the rising and falling edges of the clock input. A low jitter, symmetrical clock will provide the highest level of performance. The recommended logic families to drive the clock input are HC and F. The AD773's minimum clock half cycle may necessitate the use of an external divide-by-two circuit as shown in Figure 18. Power dissipation will vary with input clock frequency. Figure 19 shows the AD773's power dissipation vs. input clock frequency.

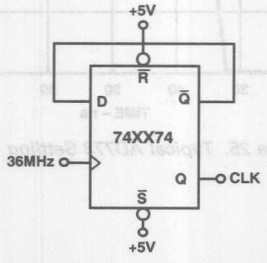

Figure 18. Divide-by-Two Clock Circuit

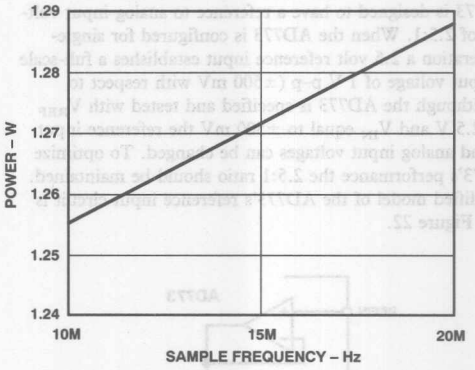

Figure 19. Power Dissipation vs. Sample Frequency

EQUIVALENT ANALOG INPUT CIRCUIT

The AD773 equivalent analog input circuit is shown in Figure 20. The typical input bias current is 5 µA, while input capacitance is typically 5 pF. In the single-ended input configuration one input is connected to AGND while the second input is driven to full scale (±500 mV). Under nominal conditions the collector of the input transistor is at +1.15 V. This allows signals to be offset by up to +0.65 V without significantly degrading performance. In the negative direction, the emitter of the input transistor should not drop below −1.25 V. Therefore, signals can be offset by −0.65 V without significant performance degradation. Figure 21 shows signal-to-noise ratio vs. common-mode input voltage.

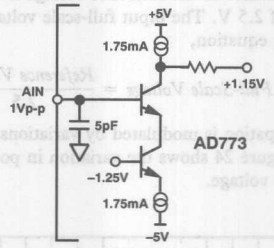

Figure 20. Equivalent Analog Input Circuit

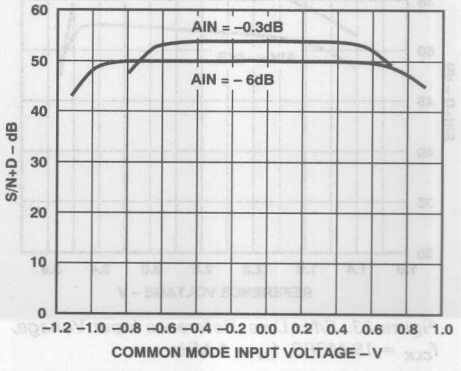

Figure 21. S/N+D vs. Common-Mode Input Voltage, f_{CLK} = 18 MSPS

EQUIVALENT REFERENCE INPUT CIRCUIT

The AD773 is designed to have a reference to analog input voltage ratio of 2.5:1. When the AD773 is configured for single-ended operation a 2.5 volt reference input establishes a full-scale analog input voltage of 1 V p–p (±500 mV with respect to V_{INB}). Although the AD773 is specified and tested with V_{REF} equal to 2.5 V and V_{IN} equal to ±500 mV the reference input voltage and analog input voltages can be changed. To optimize the AD773's performance the 2.5:1 ratio should be maintained. The simplified model of the AD773's reference input circuit is shown in Figure 22.

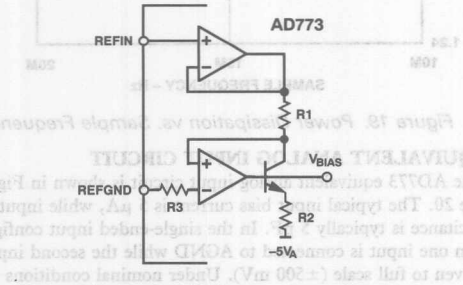

Figure 22. Typical Reference Input Circuit

The 2.5 V external reference is applied across resistor R1 producing a current which in turn generates a voltage V_{BIAS}. Multiple reference currents are generated from V_{BIAS} and are used throughout the converter. R3 is used to cancel errors induced by the input bias current of the REFGND buffer. Figure 23 shows the SNR performance as the reference voltage is varied from its nominal value of 2.5 V. The input full-scale voltage is defined by the following equation,

$$\textit{Input Full-Scale Voltage} = \frac{\textit{Reference Voltage}}{2.5}$$

The power dissipation is modulated by variations in the reference voltage. Figure 24 shows the variation in power dissipation versus reference voltage.

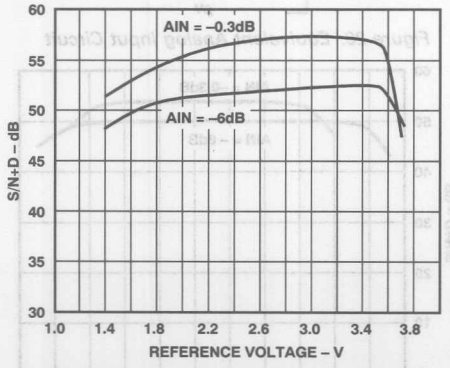

Figure 23. S/N+D vs. Reference Input Voltage, f_{CLK} = 18 MSPS, f_{IN} = 1 MHz

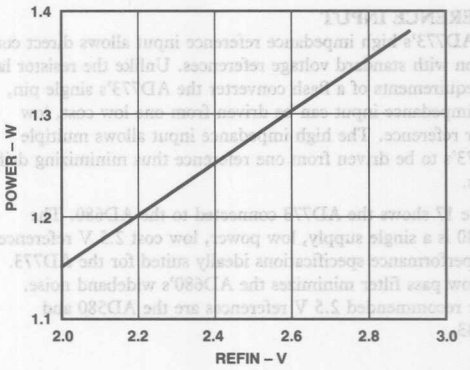

Figure 24. Power Dissipation vs. Reference Input Voltage

TRANSIENT RESPONSE

The fast settling input THA accurately converts full-scale input voltage swings in under one clock cycle. The THA's high impedance, fast slewing performance is critical in multiplexed or dc stepped (charge coupled devices, infrared detectors) systems. Figure 25 show the AD773's settling performance with an input signal stepped from −500 mV to 0V. As can be seen, the output code settles to its final value in under one clock cycle.

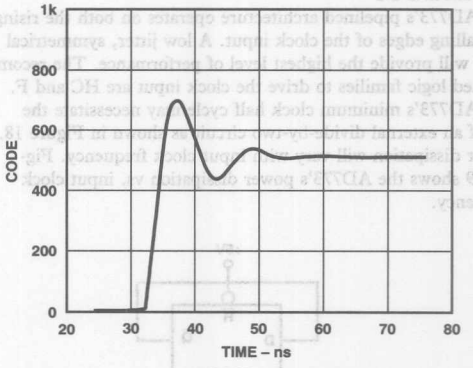

Figure 25. Typical AD773 Settling Time

OUTPUT DATA FORMAT

The AD773 provides both MSB and $\overline{MSB}$ outputs, delivering positive true offset binary and twos complement output data. Table II shows the AD773's output data format.

Table II. Output Data Format

Analog Input	Digital Output		
V_{INA}–V_{INB}	Offset Binary	Twos Complement	OTR
≥499.5 mV	11 1111 1111	01 1111 1111	1
499 mV	11 1111 1111	01 1111 1111	0
0 mV	10 0000 0000	00 0000 0000	0
−500 mV	00 0000 0000	10 0000 0000	0
≤−500.5 mV	00 0000 0000	10 0000 0000	1

OUT OF RANGE

An out-of-range condition exists when the analog input voltage is beyond the input range (±500 mV) of the converter. [Note the AD773 has a 4 clock cycle latency rating.] OTR (Pin 20) is set low when the analog input voltage is within the analog input range. OTR is set HIGH and will remain HIGH when the analog input voltage exceeds the input range by 1/2 LSB from the center of the ± full-scale output codes. OTR will remain HIGH until the analog input is within the input range. By logical ANDing OTR with the MSB and its complement, overrange high or underrange low conditions can be detected. Table III is a truth table for the over/under range circuit in Figure 26. Systems requiring programmable gain conditioning prior to the AD773 can immediately detect an out of range condition, thus eliminating gain selection iterations.

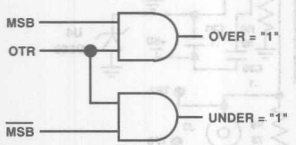

Figure 26. Overrange or Underrange Logic

Table III. Out-of-Range Truth Table

OTR	MSB	ANALOG INPUT IS
0	0	In Range
0	1	In Range
1	0	Underrange
1	1	Overrange

GROUNDING AND LAYOUT RULES

As is the case for any high performance device, proper grounding and layout techniques are essential in achieving optimal performance. The analog and digital grounds on the AD773 have been separated to optimize the management of return currents in a system. It is recommended that a 4-layer printed circuit board (PCB) which employs ground planes and power planes be used with the AD773. The use of ground and power planes offers distinct advantages:

1. The minimization of the loop area encompassed by a signal and its return path.
2. The minimization of the impedance associated with ground and power paths.
3. The inherent distributed capacitor formed by the power plane, PCB insulation, and ground plane.

These characteristics result in both a reduction of electromagnetic interference (EMI) and an overall improvement in performance.

It is important to design a layout which prevents noise from coupling onto the input signal. The wide input bandwidth of the AD773 permits noise outside the desired Nyquist bandwidth to be digitized along with the desired signal. This can result in a higher overall level of spurious noise in the digitized spectrum. Digital signals should not be run in parallel with the input signal traces and should be routed away from the input circuitry. It is also suggested that the traces associated with V_{INA} and V_{INB} be the same length.

Separate analog and digital ground should be joined together directly under the AD773 (see Figure 30). A solid ground plane under the AD773 is also acceptable if care is taken in the management of the power and ground return currents. A general "rule-of-thumb" for mixed signal layouts dictate that the return currents from digital circuitry should not pass through critical analog circuitry.

POWER SUPPLY DECOUPLING

The analog and digital supplies of the AD773 have been separated to prevent the typically large transients associated with digital circuitry from coupling into the analog supplies (AV_{DD}, AV_{SS}). Each power supply pin should be decoupled with a 0.1 μF capacitor located as close to the pin as possible. Additional 0.1 μF capacitors in parallel with the DRV_{DD} and DDV_{DD} bypass capacitors are required to adequately suppress high capacitors are recommended. The inductance associated with the leads of through-hole ceramic capacitors typically render them ineffective at higher frequencies. A *complete* system will also incorporate tantalum capacitors in the 10–100 μF range to decouple low frequency noise and ferrite beads to limit high frequency noise.

The digital supplies have additionally been separated into DRV_{DD} and DV_{DD}. The DRV_{DD} pins provide power for the digital output drivers of the AD773 and are likely to contain high energy transients. Pin 22 should be decoupled directly to Pin 21 (DRGND) and Pin 7 should be decoupled directly to Pin 8 (DRGND) to minimize the length of the return path for these transients. A single +5 V supply is all that is required for DRV_{DD} and DV_{DD}, but decoupling DV_{DD} with an RC filter network is suggested (see Figure 27).

16-Bit 100 kSPS Oversampling ADC

AD776

FEATURES
Monolithic 16-Bit ADC
Third-Order Noise Shaping
96 dB Dynamic Range
90 dB S/(N+D)
16-Bit 100 kHz Output from FIR Filter
12-Bit 400 kHz Output from Comb Filter
No Missing Codes
<0.001 dB In-Band Ripple

PIN CONFIGURATION

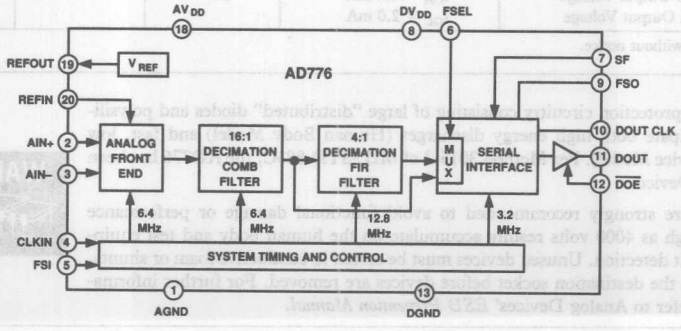
PRODUCT DESCRIPTION

The AD776 is a 16-bit sigma-delta oversampled ADC, incorporating a 1-bit noise shaping modulator and third order digital decimating filter. An on-chip voltage reference circuit is also included.

The AD776 does not require the use of sample-hold circuits or antialiasing filters as a result of its sigma-delta architecture. The output is available both before and after the final Finite Impulse Response (FIR) decimation filter. This provides the flexibility of optimizing conversion speed or resolution: 12-bit/400 kHz (from the Comb filter) or 16-bit/100 kHz (from the FIR filter). The AD776 may be used with an input multiplexer at a minimum output sampling period of 15 μs in the Comb filter output mode.

The AD776 is specified for ac (or "dynamic") parameters such as S/N+D Ratio, THD and IMD which are important in signal processing and audio applications.

The AD776 operates from a single +5 V supply and typically consumes 350 mW during conversion.



The AD776 is available in a 20-pin ceramic DIP (cerdip) or 20-pin plastic DIP package.

PRODUCT HIGHLIGHTS

1. Linear phase analog front end
2. Fully differential inputs
3. Serial Output Directly Compatible with a variety of processors
4. No sample-hold circuits or antialias filter required
5. 6.4 MHz maximum input sample rate
6. 12.8 MHz maximum internal clock rate

CAUTION

The AD776 features input protection circuitry consisting of large "distributed" diodes and polysilicon series resistors to dissipate both high energy discharges (Human Body Model) and fast, low energy pulses (Charged Device Model). Per Method 3015.2 of MIL-STD-883C, the AD776 has been classified as a Category 1 Device.

Proper ESD precautions are strongly recommended to avoid functional damage or performance degradation. Charges as high as 4000 volts readily accumulate on the human body and test equipment, and discharge without detection. Unused devices must be stored in conductive foam or shunts, and the foam discharged to the destination socket before devices are removed. For further information on ESD precaution, refer to Analog Devices' *ESD Prevention Manual*.

14-Bit 128 kSPS Complete Sampling ADC

AD779*

FEATURES

- AC and DC Characterized and Specified (K, B, T Grades)
- 128k Conversions per Second
- 1 MHz Full Power Bandwidth
- 500 kHz Full Linear Bandwidth
- 80 dB S/N+D (K, B, T Grades)
- Twos Complement Data Format (Bipolar Mode)
- Straight Binary Data Format (Unipolar Mode)
- 10 MΩ Input Impedance
- 16-Bit Bus Interface (See AD679 for 8-Bit Interface)
- On-Board Reference and Clock
- 10 V Unipolar or Bipolar Input Range
- MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD779 is a complete, multipurpose 14-bit monolithic analog-to-digital converter, consisting of a sample-hold amplifier (SHA), a microprocessor compatible bus interface, a voltage reference and clock generation circuitry.

The AD779 is specified for ac (or "dynamic") parameters such as S/N+D ratio, THD and IMD which are important in signal processing applications. In addition, the AD779K, B and T grades are fully specified for dc parameters which are important in measurement applications.

The 14 data bits are accessed by a 16-bit bus in a single read operation. Data format is straight binary for unipolar mode and twos complement binary for bipolar mode. The input has a full-scale range of 10 V with a full power bandwidth of 1 MHz and a full linear bandwidth of 500 kHz. High input impedance (10 MΩ) allows direct connection to unbuffered sources without signal degradation.

This product is fabricated on Analog Devices' BiMOS process, combining low power CMOS logic with high precision, low noise bipolar circuits; laser-trimmed thin-film resistors provide high accuracy. The converter utilizes a recursive subranging algorithm which includes error correction and flash converter circuitry to achieve high speed and resolution.

The AD779 operates from +5 V and ±12 V supplies and dissipates 560 mW (typ). Twenty-eight-pin plastic DIP, ceramic DIP, and 44-J-leaded ceramic surface mount packages are available.

***Protected by U.S. Patent Numbers 4,804,960; 4,814,767; 4,833,345; 4,250,445; 4,808,908; RE30,586.**

PRODUCT HIGHLIGHTS

1. COMPLETE INTEGRATION: The AD779 minimizes external component requirements by combining a high speed sample-hold amplifier (SHA), ADC, 5 V reference, clock and digital interface on a single chip. This provides a fully specified sampling A/D function unattainable with discrete designs.
2. SPECIFICATIONS: The AD779K, B and T grades provide fully specified and tested ac and dc parameters. The AD779J, A and S grades are specified and tested for ac parameters; dc accuracy specifications are shown as typicals. DC specifications (such as INL, gain and offset) are important in control and measurement applications. AC specifications (such as S/N+D ratio, THD and IMD) are of value in signal processing applications.
3. EASE OF USE: The pinout is designed for easy board layout, and the single cycle read output provides compatibility with 16-bit buses. Factory trimming eliminates the need for calibration modes or external trimming to achieve rated performance.
4. RELIABILITY: The AD779 utilizes Analog Devices' monolithic BiMOS technology. This ensures long term reliability compared to multichip and hybrid designs.
5. The AD779 is available in versions compliant with MIL-STD-883. Refer to the Analog Devices Military Products Databook or current AD779/883B data sheet for detailed specifications.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

2

ESD SENSITIVITY

The AD779 features input protection circuitry consisting of large "distributed" diodes and polysilicon series resistors to dissipate both high energy discharges (Human Body Model) and fast, low energy pulses (Charged Device Model). Per Method 3015.2 of MIL-STD-883C, the AD779 has been classified as a Category 1 device.

Proper ESD precautions are strongly recommended to avoid functional damage or performance degradation. Charges as high as 4000 volts readily accumulate on the human body and test equipment and discharge without detection. Unused devices must be stored in conductive foam or shunts, and the foam should be discharged to the destination socket before devices are removed. For further information on ESD precautions, refer to Analog Devices' *ESD Prevention Manual*.

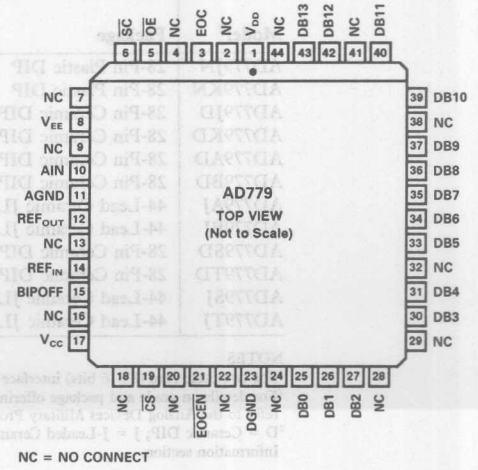
AD779 PIN DESCRIPTION

Symbol	28-Pin DIP Pin No.	44-Lead JLCC Pin No.	Type	Name and Function
AGND	7	11	P	Analog Ground. This is the ground return for AIN only.
AIN	6	10	AI	Analog Signal Input.
BIPOFF	10	15	AI	Bipolar Offset. Connect to AGND for +10 V input unipolar mode and straight binary output coding. Connect to REF_{OUT} for ±5 V input bipolar mode and twos-complement binary output coding.
$\overline{CS}$	12	19	DI	Chip Select. Active LOW.
DGND	14	23	P	Digital Ground
DB13–DB0	28–15	43, 42, 40, 39, 37, 36, 35, 34, 33, 31, 30, 27, 26, 25	DO	Data Bits. These pins provide all 14 bits in one 14 bit parallel output. Active HIGH
EOC	2	3	DO	End-of-Convert. EOC goes LOW when a conversion starts and goes HIGH when the conversion is finished. EOC is a three-state output. See $\overline{EOCEN}$ pin for information on EOC gating.
$\overline{EOCEN}$	13	21	DI	End-of-Convert Enable. Enables EOC pin. Active LOW.
$\overline{OE}$	3	5	DI	Output Enable. A down-going transition on $\overline{OE}$ enables data bits. Active LOW.
REF_{IN}	9	14	AI	Reference Input. +5 V input gives 10 V full scale range.
REF_{OUT}	8	12	AO	+5 V Reference Output. Tied to REF_{IN} for normal operation.
$\overline{SC}$	4	6	DI	Start Convert. Active LOW.
V_{CC}	11	17	P	+12 V Analog Power.
V_{EE}	5	8	P	−12 V Analog Power.
V_{DD}	1	1	P	+5 V Digital Power.



Type: AI = Analog Input.
AO = Analog Output.
DI = Digital Input.
DO = Digital Output. All DO pins are three-state drivers.
P = Power.

PIN CONFIGURATIONS

DIP Package

JLCC Package

NC = NO CONNECT

NYQUIST FREQUENCY
An implication of the Nyquist sampling theorem, the "Nyquist Frequency" of a converter is that input frequency which is one-half the sampling frequency of the converter.

SIGNAL-TO-NOISE AND DISTORTION (S/N+D) RATIO
S/N+D is the ratio of the rms value of the measured input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc.

TOTAL HARMONIC DISTORTION (THD)
THD is the ratio of the rms sum of the first six harmonic components to the rms value of a full-scale input signal and is expressed as a percentage or in decibels. For input signals or harmonics that are above the Nyquist frequency, the aliased component is used.

PEAK SPURIOUS OR PEAK HARMONIC COMPONENT
The peak spurious or peak harmonic component is the largest spectral component excluding the input signal and dc. This value is expressed in decibels relative to the rms value of a full-scale input signal.

INTERMODULATION DISTORTION (IMD)
With inputs consisting of sine waves at two frequencies, fa and fb, any device with nonlinearities will create distortion products, of order (m + n), at sum and difference frequencies of mfa ± nfb, where m, n = 0, 1, 2, 3 . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are (fa + fb) and (fa − fb) and the third order terms are (2 fa + fb), (2 fa − fb), (fa + 2 fb) and (fa − 2 fb). The IMD products are expressed as the decibel ratio of the rms sum of the measured input signals to the rms sum of the distortion terms. The two signals applied to the converter are of equal amplitude and the peak value of their sum is −0.5 dB from full scale (9.44 V p–p). The IMD products are normalized to a 0-dB input signal.

BANDWIDTH
The full-power bandwidth is that input frequency at which the amplitude of the reconstructed fundamental is reduced by 3 dB for a full-scale input.

The full-linear bandwidth is the input frequency at which the slew rate limit of the sample-hold-amplifier (SHA) is reached. At this point, the amplitude of the reconstructed fundamental has degraded by less than −0.1 dB. Beyond this frequency, distortion of the sampled input signal increases significantly.

The AD779 has been designed to optimize input bandwidth, allowing it to undersample input signals with frequencies significantly above the converter's Nyquist frequency.

APERTURE DELAY
Aperture delay is a measure of the SHA's performance and is measured from the falling edge of Start Convert ($\overline{SC}$) to when the input signal is held for conversion.

APERTURE JITTER
Aperture jitter is the variation in aperture delay for successive samples and is manifested as noise on the input to the A/D.

INPUT SETTLING TIME
Settling time is a function of the SHA's ability to track fast slewing signals. This is specified as the maximum time required in track mode after a full-scale step input to guarantee rated conversion accuracy.

DIFFERENTIAL NONLINEARITY (DNL)
In an ideal ADC, code transitions are 1 LSB apart. Differential linearity is the deviation from this ideal value. It is often specified in terms of resolution for which no missing codes (NMC) are guaranteed.

INTEGRAL NONLINEARITY (INL)
The ideal transfer function for a linear ADC is a straight line drawn between "zero" and "full scale." The point used as "zero" occurs 1/2 LSB before the first code transition. "Full scale" is defined as a level 1 1/2 LSB beyond the last code transition. Integral nonlinearity error is the worst case deviation of a code from the straight line. The deviation of each code is measured from the middle of that code.

Note that the linearity error is not user adjustable.

POWER SUPPLY REJECTION
Variations in power supply will affect the full-scale transition, but not the converter's linearity. Power Supply Rejection is the maximum change in the full-scale transition point due to a change in power supply voltage from the nominal value.

TEMPERATURE DRIFT
This is the maximum change in the parameter from the initial value (@+25°C) to the value at T_{min} or T_{max}.

UNIPOLAR ZERO ERROR
In unipolar mode, the first transition should occur at a level 1/2 LSB above analog ground. Unipolar zero error is the deviation of the actual transition from that point. This error can be adjusted as discussed in the Input Connections and Calibration section.

BIPOLAR ZERO ERROR
In the bipolar mode, the major carry transition (11 1111 1111 1111 to 00 0000 0000 0000) should occur at an analog value 1/2 LSB below analog ground. Bipolar zero error is the deviation of the actual transition from that point. This error can be adjusted as discussed in the Input Connections and Calibration section.

GAIN ERROR
The last transition should occur at an analog value 1 1/2 LSB below the nominal full scale (9.9991 volts for a 0–10 V range, 4.9991 volts for a ±5 V range). The gain error is the deviation of the actual level at the last transition from the ideal level with the zero error trimmed out. This error can be adjusted as shown in the Input Connections and Calibration section.

bringing $\overline{SC}$ LOW, regardless of the state of $\overline{CS}$.

After a conversion is started, the sample-hold goes into hold mode and EOC goes LOW, signifying that a conversion is in progress. During the conversion, the sample-hold will go back into track mode and start acquiring the next sample.

In track mode, the sample-hold will settle to ±0.003% (14 bits) in 1.5 μs maximum. The acquisition time does not affect the throughput rate as the AD779 goes back into track mode more than 2 μs before the next conversion. In multichannel systems, the input channel can be switched as soon as EOC goes LOW if the maximum throughput rate is needed.

When EOC goes HIGH, the conversion is completed and the output data may be read. Bringing $\overline{OE}$ LOW makes the output register contents available on the output data bits (DB13–DB0). A period of time t_{CD} is required after $\overline{OE}$ is brought HIGH before the next $\overline{SC}$ instruction is issued.

If $\overline{SC}$ is held LOW, conversion accuracy may deteriorate. For this reason, $\overline{SC}$ should not be held low in any attempt to operate in a continuously converting mode.

END-OF-CONVERT

End-of-Convert (EOC) is a three-state output which is enabled by End-of-Convert Enable $\overline{EOCEN}$.

CONVERSION TRUTH TABLE

	INPUTS				OUTPUTS	
Mode	$\overline{SC}$	$\overline{EOCEN}$	$\overline{CS}$	$\overline{OE}$	EOC DB13 . . . DB0	Status
Start Conversion	1	X	X	X		No Conversion
	↓	X	X	X		Start Conversion
	0	X	X	X		Continuous Conversion (Not Recommended)
Conversion Status	X	0	X	X	0	Converting
	X	0	X	X	1	Not Converting
	X	1	X	X	High Z	Either
Data Access	X	X	X	1	High Z	Three-State
	X	X	1	X	High Z	Three-State
	X	X	0	0	MSB . . . LSB	Data Out

NOTES
1 = HIGH voltage level.
0 = LOW voltage level.
X = Don't care.
↓ = HIGH to LOW transition. Must stay LOW for $t = t_{CP}$.

be LOW t_{OE} before $\overline{OE}$ is brought LOW. The output is read in a single cycle as a 14-bit word.

In unipolar mode (BIPOFF tied to AGND), the output coding is straight binary. In bipolar mode (BIPOFF tied to REF_{OUT}), output coding is twos complement binary.

POWER-UP

The AD779 typically requires 10 μs after power-up to reset internal logic.

14-BIT MODE CODING FORMAT (1 LSB = 0.61 mV)

Unipolar Coding (Straight Binary)		Bipolar Coding (Twos Complement)	
V_{IN}	Output Code	V_{IN}	Output Code
0.00000 V	000 . . . 0	−5.00000 V	100 . . . 0
5.00000 V	100 . . . 0	−0.00061 V	111 . . . 1
9.99939 V	111 . . . 1	0.00000 V	000 . . . 0
		+2.50000 V	010 . . . 0
		+4.99939 V	011 . . . 1

INPUT CONNECTIONS AND CALIBRATION

The high (10 MΩ) input impedance of the AD779 eases the task of interfacing to high source impedances or multiplexer channel-to-channel mismatches of up to 300 Ω. The 10 V p-p full scale input range accepts the majority of signal voltages without the need for voltage divider networks which could deteriorate the accuracy of the ADC.

The AD779 is factory trimmed to minimize offset, gain and linearity errors. In unipolar mode, the only external component that is required is a 50 Ω ±1% resistor. Two resistors are required in bipolar mode. If offset and gain are not critical, even these components can be eliminated.

In some applications, offset and gain errors need to be more precisely trimmed. The following sections describe the correct procedure for these various situations.

BIPOLAR RANGE INPUTS

The connections for the bipolar mode are shown in Figure 5. In this mode, data output coding will be twos complement binary. This circuit will allow approximately ±25 mV of offset trim range (±40 LSB) and ±0.5% of gain trim range (±80 LSB).

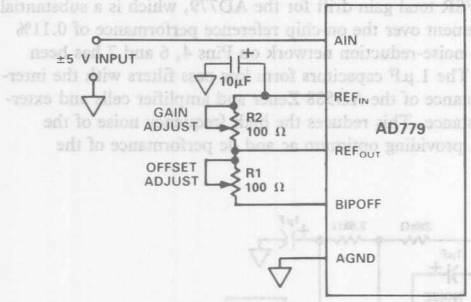


Figure 5. Bipolar Input Connections with Gain and Offset Trims

Either or both of the trim pots can be replaced with 50 Ω ±1% fixed resistors if the AD779 accuracy limits are sufficient for the application. If the pins are shorted together, the additional offset and gain errors will be approximately 80 LSB.

To trim bipolar zero to its nominal value, apply a signal 1/2 LSB below midrange (−0.305 mV for a ±5 V range) and adjust R1 until the major carry transition is located (11 1111 1111 1111 to 00 0000 0000 0000). To trim the gain, apply a signal 1 1/2 LSB below full scale (+4.9991 V for a ±5 V range) and adjust R2 to give the last positive transition (01 1111 1111 1110 to 01 1111 1111 1111). These trims are interactive so several iterations may be necessary for convergence.

A single pass calibration can be done by substituting a bipolar offset trim (error at minus full scale) for the bipolar zero trim (error at midscale), using the same circuit. First, apply a signal 1/2 LSB above minus full scale (−4.9997 V for a ±5 V range) and adjust R1 until the minus full scale transition is located (10 0000 0000 0000 to 10 000 000 0001). Then perform the gain error trim as outlined above.

UNIPOLAR RANGE INPUTS

Offset and gain errors can be trimmed out by using the configuration shown in Figure 6. This circuit allows approximately ±25 mV of offset trim range (±40 LSB) and ±0.5% of gain trim range (±80 LSB).

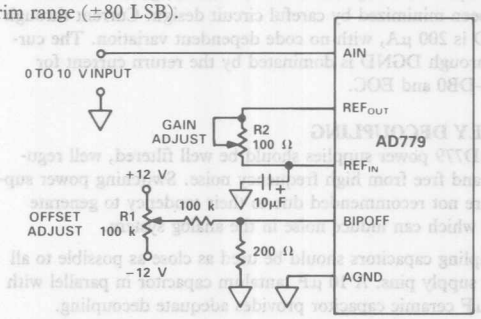

Figure 6. Unipolar Input Connections with Gain and Offset Trims

The first transition (from 00 0000 0000 0000 to 00 0000 0000 0001) should nominally occur for an input level of +1/2 LSB (0.305 mV above ground for a 10 V range). To trim unipolar zero to this nominal value, apply a 0.305 mV signal to AIN and adjust R1 until the first transition is located.

The gain trim is done by adjusting R2. If the nominal value is required, apply a signal 1 1/2 LSB below full scale (9.9997 V for a 10 V range) and adjust R2 until the last transition is located (11 1111 1111 1110 to 11 1111 1111 1111).

If offset adjustment is not required, BIPOFF should be connected directly to AGND. If gain adjustment is not required, R2 should be replaced with a fixed 50 Ω ±1% metal film resistor. If REF_{OUT} is connected directly to REF_{IN}, the additional gain error will be approximately 1%.

REFERENCE DECOUPLING

It is recommended that a 10 µF tantalum capacitor be connected between REF_{IN} (Pin 9) and ground. This has the effect of improving the S/N+D ratio through filtering possible broadband noise contributions from the voltage reference.

BOARD LAYOUT

Designing with high resolution data converters requires careful attention to board layout. Trace impedance is a significant issue. A 1.22 mA current through a 0.5 Ω trace will develop a voltage drop of 0.6 mV, which is 1 LSB at the 14-bit level for a 10 V full scale span. In addition to ground drops, inductive and capacitive coupling need to be considered, especially when high accuracy analog signals share the same board with digital signals. Finally, power supplies need to be decoupled in order to filter out ac noise.

Analog and digital signals should not share a common path. Each signal should have an appropriate analog or digital return routed close to it. Using this approach, signal loops enclose a small area, minimizing the inductive coupling of noise. Wide PC tracks, large gauge wire, and ground planes are highly recommended to provide low impedance signal paths. Separate analog and digital ground planes are also desirable, with a single interconnection point to minimize ground loops. Analog signals should be routed as far as possible from digital signals and should cross them at right angles.

The AD779 incorporates several features to help the user's layout. Analog pins (V_{EE}, AIN, AGND, REF_{OUT}, REF_{IN}, BIPOFF, V_{CC}) are adjacent to help isolate analog from digital signals. In addition, the 10 MΩ input impedance of AIN minimizes input trace impedance errors. Finally, ground currents have been minimized by careful circuit design. Current through AGND is 200 μA, with no code dependent variation. The current through DGND is dominated by the return current for DB13–DB0 and EOC.

SUPPLY DECOUPLING

The AD779 power supplies should be well filtered, well regulated, and free from high frequency noise. Switching power supplies are not recommended due to their tendency to generate spikes which can induce noise in the analog system.

Decoupling capacitors should be used as close as possible to all power supply pins. A 10 μF tantalum capacitor in parallel with a 0.1 μF ceramic capacitor provides adequate decoupling.

An effort should be made to minimize the trace length between the capacitor leads and the respective converter power supply and common pins. The circuit layout should attempt to locate the AD779, associated analog input circuitry and interconnections as far as possible from logic circuitry. A solid analog ground plane around the AD779 will isolate large switching ground currents. For these reasons, the use of wire wrap circuit construction is not recommended; careful printed circuit construction is preferred.

GROUNDING

If a single AD779 is used with separate analog and digital ground planes, connect the analog ground plane to AGND and the digital ground plane to DGND keeping lead lengths as short as possible. Then connect AGND and DGND together at the AD779. If multiple AD779s are used or the AD779 shares analog supplies with other components, connect the analog and digital returns together once at the power supplies rather than at each chip. This prevents large ground loops which inductively couple noise and allow digital currents to flow through the analog system.

USE OF EXTERNAL VOLTAGE REFERENCE

The AD779 features an on-chip voltage reference. For improved gain accuracy over temperature, a high performance external voltage reference may be used in place of the on-chip reference.

The AD586 and AD588 are popular references appropriate for use with high resolution converters. The AD586 is a low cost reference which utilizes a buried Zener architecture to provide low noise and drift. The AD588 is a higher performance reference which uses a proprietary ion-implanted buried Zener diode in conjunction with laser-trimmed thin-film resistors for low offset and low drift.

Figure 7 shows the use of the AD586 with the AD779 in a bipolar input mode. Over the 0 to +70°C range, the AD586 L-grade exhibits less than a 2.25 mV output change from its initial value at 25°C. REF_{IN} (Pin 9) scales its input by a factor of two; thus, this change becomes effectively 4.5 mV. When applied to the AD779, this results in a total gain drift of 0.09% FSR which is an improvement over the on-chip reference performance of 0.11% FSR. A noise-reduction capacitor, C_N, has been shown. This capacitor reduces the broadband noise of the AD586 output, thereby optimizing the overall ac and dc performance of the AD779.

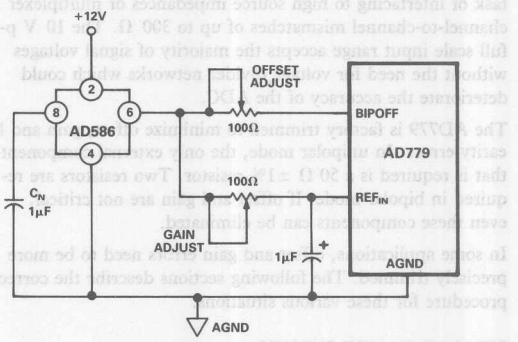

Figure 7. Bipolar Input with Gain and Offset Trims

Figure 8 shows the AD779 in unipolar input mode with the AD588 reference. The AD588 output is accurate to 0.65 mV from its value at 25°C over the 0 to 70°C range. This results in a 0.06% FSR total gain drift for the AD779, which is a substantial improvement over the on-chip reference performance of 0.11% FSR. A noise-reduction network on Pins 4, 6 and 7 has been shown. The 1 μF capacitors form low pass filters with the internal resistance of the AD588 Zener and amplifier cells and external resistance. This reduces the high frequency noise of the AD588, providing optimum ac and dc performance of the AD779.

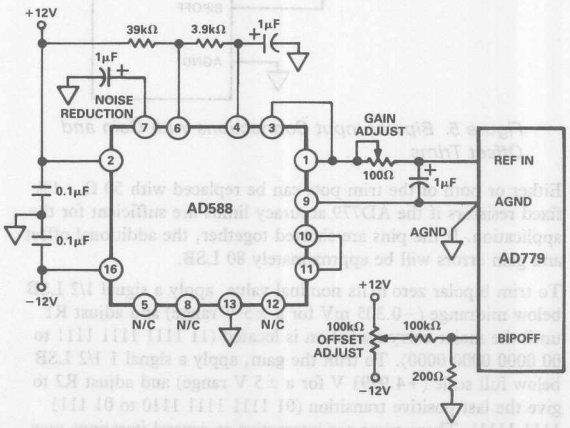

Figure 8. Unipolar Input with Gain and Offset Trims

INTERFACING THE AD779 TO MICROPROCESSORS

The I/O capabilities of the AD779 allow direct interfacing to general purpose and DSP microprocessor buses. The asynchronous conversion control feature allows complete flexibility and control with minimal external hardware.

The following examples illustrate typical AD779 interface configurations.

In Figure 9 the AD779 is mapped into the TMS320C25 I/O space. AD779 conversions are initiated by issuing an OUT instruction to Port 1. EOC status and the conversion result are read in with an IN instruction to Port 1. A single wait state is inserted by generating the processor READY input from $\overline{IS}$, Port 1 and $\overline{MSC}$. This configuration supports processor clock speeds of 20 MHz and is capable of supporting processor clock speeds of 40 MHz if a NOP instruction follows each AD779 read instruction.

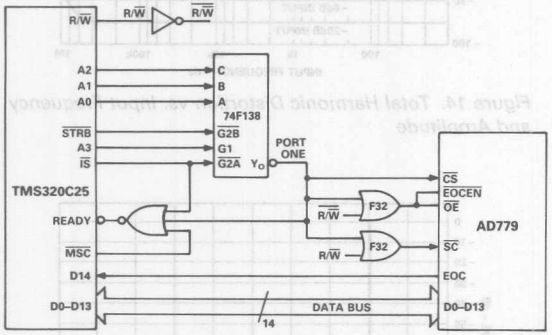

Figure 9. AD779 to TMS320C25 Interface

AD779 TO 80186

Figure 10 shows the AD779 interfaced to the 80186 microprocessor. This interface allows the 80186's built-in DMA controller to transfer the AD779 output into a RAM based FIFO buffer of any length, with no microprocessor intervention.

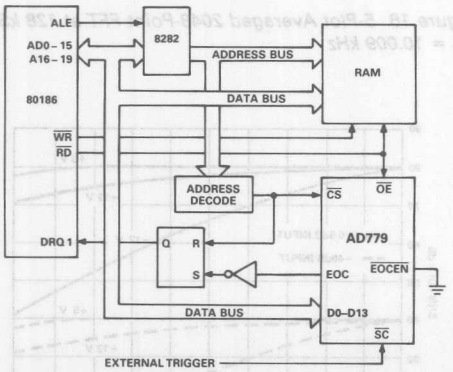

Figure 10. AD779 to 80186 DMA Interface

AD779 TO Z80

The AD779 can be interfaced to the Z80 processor in an I/O or memory mapped configuration. Figure 11 illustrates an I/O configuration, where the AD779 occupies several port addresses to allow separate polling of the EOC status and reading of the data. A useful feature of the Z80 is that a single wait state is automatically inserted during I/O operations, allowing the AD779 to be used with Z80 processors having clock speeds up to 8 MHz.

tiated by an external trigger source independent of the microprocessor clock. After each conversion, the AD779 EOC signal generates a DMA request to Channel 1 (DRQ1). The subsequent DMA READ resets the interrupt latch. The system designer must assign a sufficient priority to the DMA channel to ensure that the DMA request will be serviced before the completion of the next conversion. This configuration can be used with 6 MHz and 8 MHz 80186 processors.

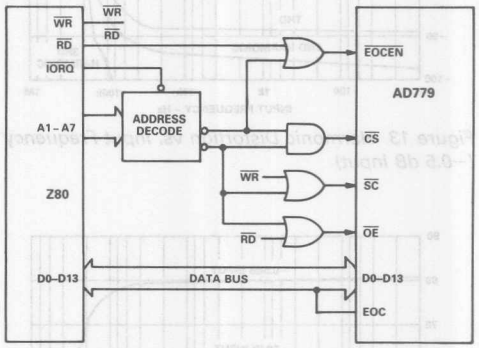

Figure 11. AD779 to Z80 Interface

AD779 TO ANALOG DEVICES ADSP-2100A

Figure 12 demonstrates the AD779 interfaced to an ADSP-2100A. With a clock frequency of 12.5 MHz, and instruction execution in one 80 ns cycle, the digital signal processor will support the AD779 data memory interface with two wait states.

The converter runs asychronously using a sampling clock. The EOC output to the AD779 gets asserted at the end of each conversion and causes an interrupt. Upon interrupt, the ADSP-2100A starts a data memory read by providing an address on the DMA bus. The decoded address generates $\overline{OE}$ for the converter. $\overline{OE}$, together with logic and latch, is used to force the ADSP-2100A into a one cycle wait state by generating DMACK. The read operation is thus started and completed within two processor cycles (160 ns).

High Resolution, Programmable Integrating A/D Converter

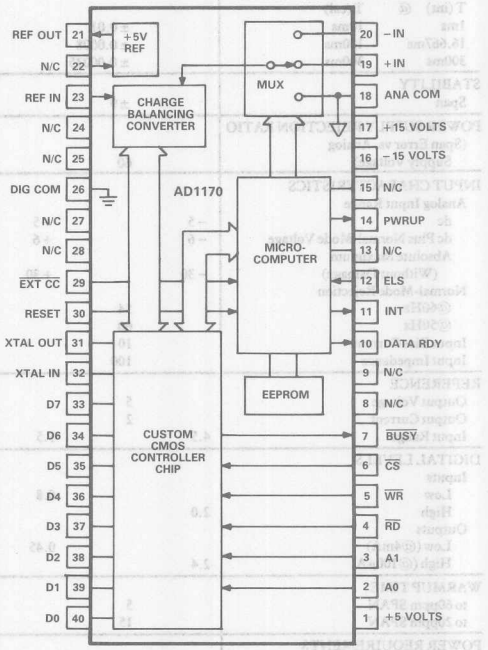
AD1170

FEATURES

Low Nonlinearity:
- **Integral: ±0.001%**
- **Differential: ±0.00035%**

Microcomputer-Based Design
- **Programmable Integration Time: 1 to 350ms with Resolution from 7 to 18 Bits**
- **Programmable Output Data Format**
- **Auto-Zeroed Operation and Electronic Calibration (No External Trim Potentiometers)**
- **Microprocessor Compatible Interface**

High Throughput: Over 50 Conversions/Second for Line Cycle Integration Period



High Normal Mode Rejection: 54dB at 60Hz

Small Size: 1.24″ × 2.5″ × 0.55″ max

APPLICATIONS

Data Acquisition Systems
Scientific Instruments
Medical Instruments
Weighing Systems
Automatic Test Equipment

LEAVE N/C PINS UNCONNECTED

GENERAL DESCRIPTION

The AD1170 is a high resolution integrating A/D converter intended for applications requiring high accuracy and high throughput at low cost. A novel conversion architecture provides the user with outstanding accuracy, stability and ease of use.

The AD1170 is a complete microcomputer-based measurement subsystem, composed of three major elements: a highly precise charge balancing converter, a single chip microcomputer, and a custom CMOS controller chip. The AD1170 offers independently programmable integration time (from one millisecond to 350 milliseconds) and data format (offset binary or two's complement, from 7 to 22 bits). The converter is fully auto-zeroed and exhibits a span drift of only 9ppm/°C, assuring stable, accurate readings.

The AD1170 may be interfaced to any microcomputer based system in a memory mapped or I/O mapped fashion via an 8-bit data bus. The AD1170's advanced features are controlled by simple commands sent to it via this bus.

The converter utilizes surface mount technology and is housed in a small 1.24″ × 2.5″ × 0.55″ package. It operates from ±15V dc and +5V dc power.

PRODUCT HIGHLIGHTS

1. The AD1170, unlike dual slope converters, offers the user the capability of programming the integration time by selecting one of seven preset integration periods or by loading an arbitrary integration period over the interface bus.
2. The AD1170 architecture provides for user programmable data format independent of the integration time. All data is computed to 22-bit resolution and the user may specify any resolution from 7 to 22 bits. Usable resolution will typically be limited to 18-bits due to measurement and calibration noise error.
3. Electronic digital calibration eliminates the need for trim potentiometers. Calibration can be performed at any time by applying an external reference voltage to the input and invoking a calibration command. The calibration data is stored in an internal nonvolatile memory chip.
4. Internal calibration cycles may be programmed to occur whenever the converter is idle, assuring negligible offset drift and only 9ppm/°C span drift.
5. The conversion rate is greater than 50 conversions per second when programmed for 60Hz line cycle integration. The maximum conversion rate is greater than 250 conversions per second, using a one millisecond integration period.

AD1170—SPECIFICATIONS (typical @ +25°C, V_S = +15V, V_D = +5V unless otherwise specified.)

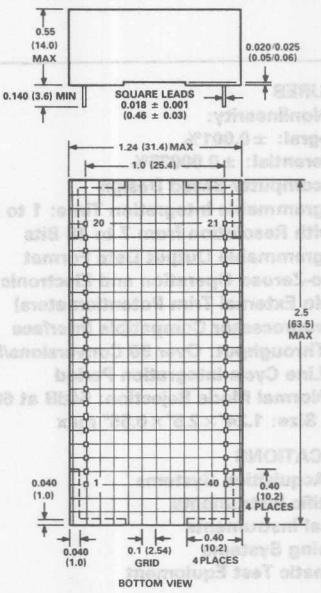
NOTES

[1]The usable resolution is limited by noise, which is largely determined by the integration period and calibration period. Consult the chart in Figure 4 for typical peak-to-peak noise versus integration and calibration period.

[2]The integral linearity is defined as the deviation from a straight line drawn between the endpoints of the converter. This specification is independent of gain and/or offset errors.

[3]Throughput Rate is calculated by the formula: $\frac{1000}{T(int) + 3 \text{ milliseconds}}$ = minimum conversions/second

Where T(int) is expressed in number of milliseconds.



Specifications subject to change without notice.

IBM PC/XT/AT compatible evaluation board:* AC5004 (see last page of this data sheet for description).

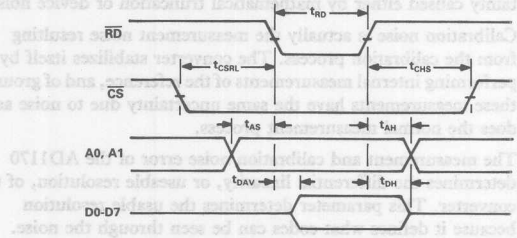
parameters as programmed by the user (such as the integration period, output data format, calibration coefficient, etc.). The AD1170 is calibrated at the factory with the following default settings:

FORMAT: 16-bit, offset binary
DEFAULT T(int): 16.667 milliseconds (code 2)
DEFAULT T(cal): 100 milliseconds (code 4)

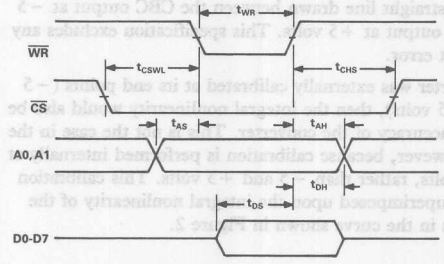
AD1170 ARCHITECTURAL OVERVIEW



The AD1170 is a complete microcomputer-based measurement subsystem, containing three major elements: a highly precise charge balancing converter, a single chip microcomputer, and a custom CMOS controller chip.

The heart of the measurement technique is the charge balancing converter (essentially a voltage to frequency converter). This converter measures the input signal by balancing a proportional current against a train of precisely controlled reference current pulses using an integrator. The microprocessor, together with the counting and gating circuitry within the CMOS controller chip, measures the period of the reference current pulses by interpolating them using a 12MHz clock signal. The resulting

When the AD1170 is triggered to perform a conversion, two separate phases are performed: first, an integration phase, where the input signal is actually measured, and then a computation phase, where the data from the integration phase is processed, along with both the volatile and nonvolatile calibration data, and formatted for output as the user desires.



The duration of the integration phase can be programmed by the user, and may be as short as one millisecond, or as long as 350 milliseconds. The computation phase always lasts approximately three milliseconds and commences immediately after the integration phase is over. Therefore, the total conversion time will equal the user programmed integrate time plus a fixed 3 milliseconds. Status signals are provided to indicate when the data is ready and when the converter may be retriggered for the next conversion.

For maximum stability, the AD1170 periodically calibrates itself by performing measurements upon a zero input signal and a full-scale signal provided by the internal reference. This technique cancels any drift within the charge balancing converter itself, resulting in negligible offset drift, and gain stability equal to that of the reference. Calibration cycles may be programmed to take place whenever the AD1170 is idle, or they may be invoked under system control.

READ CYCLE TIMING REQUIREMENTS

PARAMETER	DESCRIPTION	MIN	TYP	MAX	UNITS
t_{RD}	RD Pulse Width	150			ns
t_{CSRL}	Chip Select to RD Low	0			ns
t_{CHS}	Chip Select Hold Time	0			ns
t_{AS}	Address Setup Time	10			ns
t_{AH}	Address Hold Time	0			ns
t_{DAV}	Data Valid Time			100	ns
t_{DH}	Data Hold Time			80	ns

WRITE CYCLE TIMING REQUIREMENTS

PARAMETER	DESCRIPTION	MIN	TYP	MAX	UNITS
t_{WR}	WR Pulse Width	0.10		20	µs
t_{CSWL}	Chip Select to WR Low	0			ns
t_{CHS}	Chip Select Hold Time	0			ns
t_{AS}	Address Setup Time	10			ns
t_{AH}	Address Hold Time	0			ns
t_{DS}	Data Setup Time	80			ns
t_{DH}	Data Hold Time	20			ns

Figure 1. Timing Diagrams and Requirements

The AD1170 contains no internal trims; its span accuracy is factory calibrated by using the ECAL (Electronic CALibration) feature. This feature is a firmware routine which measures an externally applied reference voltage, compares it to the internal reference voltage, and computes a span correction factor which is stored in nonvolatile memory. The correction factor is then applied to all subsequent measurements, thereby compensating for the reference error. The ECAL function may be invoked by the user at any time, thereby replacing the usual trim potentiometer with a totally electronic calibration capability.

UNDERSTANDING THE AD1170 SPECIFICATIONS

The AD1170, because of its unique conversion technique, is specified quite differently from more conventional integrating converters. The following sections will help the user to understand where the sources of error are, and how to extract the best possible performance from the converter.

There are two primary sources of error in the AD1170: integral nonlinearity of the charge balancing converter, which influences all conversions equally, regardless of the integration period and calibration period; and the noise error of the measurement/calibration process, which is a function of the integration period and calibration period as selected by the user.

INTEGRAL NONLINEARITY

The integral nonlinearity of the charge balancing converter (CBC) is ±10ppm (±0.001%) of Span. This specification is an "endpoint" nonlinearity measurement; i.e., the typical deviation seen from a straight line drawn between the CBC output at −5 volts and its output at +5 volts. This specification excludes any gain or offset error.

If the converter was externally calibrated at its end points (−5 volts and +5 volts), then the integral nonlinearity would also be the relative accuracy of the converter. This is not the case in the AD1170, however, because calibration is performed internally at 0 and +5 volts, rather than −5 and +5 volts. This calibration technique, superimposed upon the integral nonlinearity of the CBC, results in the curve shown in Figure 2.

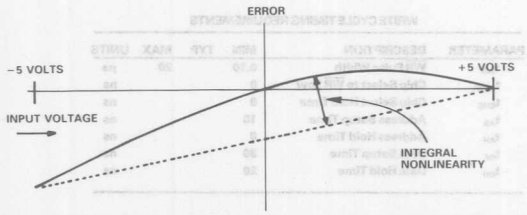


Figure 2. Relative Accuracy and Integral Nonlinearity when Calibrated

As shown in the diagram, the calibration technique tends to exaggerate the relative error at the negative end of the scale, and reduce the error between 0 and +5 volts. This characteristic happens to be most beneficial when using the AD1170 in systems where the input comes from a sensor whose signal is mostly positive, such as a thermocouple.

For systems where the user desires to minimize the relative error equally across the whole span of the converter, it is possible to intentionally introduce a span error during the ECAL procedure, as shown in Figure 3. This scheme sacrifices positive full-scale accuracy in order to minimize negative full scale error. The net result is a relative accuacy equal to the integral nonlinearity.

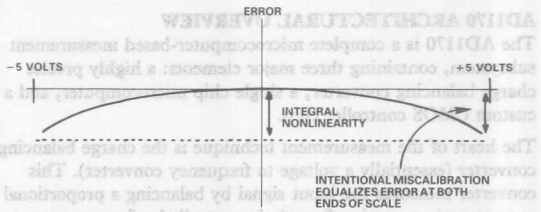

Figure 3. Relative Accuracy with Intentional Span Error at +F.S.

In both cases the accuracy of the input offset (which is servo controlled) is not compromised.

MEASUREMENT/CALIBRATION NOISE

Measurement noise refers to the conversion-to-conversion uncertainty caused either by mathematical truncation or device noise.

Calibration noise is actually the measurement noise resulting from the calibration process. The converter stabilizes itself by performing internal measurements of the reference, and of ground; these measurements have the same uncertainty due to noise as does the normal measurement process.

The measurement and calibration noise error of the AD1170 determines the differential linearity, or useable resolution, of the converter. This parameter determines the usable resolution because it defines what codes can be seen through the noise. The specified value is the amount of error, in either direction from the average reading, which will not be exceeded for 95% of all conversions. This parameter, as in all integrating converters, is a function of the integration time; long conversions result in very high resolution, while short conversions provide lower resolution. In the AD1170, all internal computations are always carried out to 22-bit resolution, but useable resolution is limited by the peak-to-peak noise, as determined by T(cal) and T(int).

The chart shown in Figure 4, illustrates the typical peak-to-peak noise (in ppm Span) versus T(int) and T(cal). These numbers can be used to indicate how much useable resolution can be

T(cal) =	1ms	10ms	16.7ms	20ms	100ms	166.7ms	300ms	CAL DISABLED	UNITS
T(int) = 1ms	208	115	115	114	113	112	111	110	±ppm of SPAN
10ms		24	18	16	13	13	13	12	
16.7ms			14	13	8	8	8	8	
20ms				12	7	7	7	7	
100ms					4.0	4.0	3.5	3.5	
166.7ms						4.0	3.5	3.5	
300ms							3.5	3.5	

Figure 4. Typical Peak-to-Peak Noise (in ppm Span) Versus T(int) and T(cal)

expected under a given set of operating conditions. For example, a peak-to-peak noise of ±8ppm is approximately analogous to a flicker of ±0.5LSB at 16 bits of resolution. Under these conditions, a user could set the default format for the AD1170 to 16-bit resolution, and observe no more than ±1/2LSB of differential error. See Table I for conversion of typical peak-to-peak noise to Differential Nonlinearity and Useable Resolution.

The chart in Figure 4 may also be used to determine the minimum effective calibration time for a specified integration period; the noise contributions of both the measurement cycle and the calibration cycle combine as the "root sum square", and the combined effect tends to asymptotically approach a baseline value determined by the shorter of the two. For example, a T(cal) greater than 10 milliseconds does little or nothing to improve the noise performance for conversions using a T(int) of 1 millisecond.

NOISE (ppm Span)	RESOLUTION AT 1/2LSB DNL ERROR (NO. OF BITS)	RESOLUTION AT 1LSB DNL ERROR (NO. OF BITS)	DIFFERENTIAL NONLINEARITY (% Span)
244	11	12	0.024
122	12	13	0.012
61	13	14	0.006
31	14	15	0.003
15	15	16	0.0015
8	16	17	0.00076
4	17	18	0.00038
2	18	19	0.00019

Table I. Conversion of Noise Error to DNL and Usable Resolution

SIGNAL INPUT CONNECTIONS

The AD1170 has both a positive input pin (+IN) as well as a negative input pin (−IN), but the AD1170 input is not a true differential input. The negative input pin is an input used during calibration cycles to establish the zero reference. In applications with static ground offsets, the −IN pin may be used as a ground sense input, to sense a signal reference point which is offset from analog common by a small differential. Both the −IN and +IN signals must have a bias current path back to analog common. Figure 5 illustrates the proper use of the input signal connections.

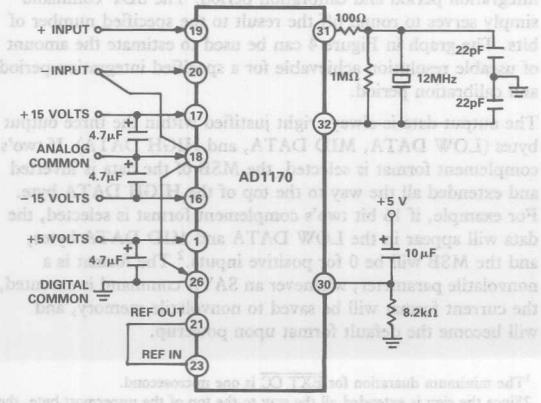

Figure 5. Input, Power, Reset, and Clock Connections

RESET

A reset sequence must be accomplished after power-up and before any access to the converter. The RESET line initializes the internal logic of the AD1170. This line may be driven from an external source, such as may exist in most computer based systems, or it may be connected to a simple RC circuit which will automatically invoke a reset sequence at power-up. Figure 5 illustrates the recommended circuit.

When driving the RESET line from an external source, the line must be held high for at least 2 microseconds after the oscillator is running and stable (typically 300 microseconds after power is applied) in order to assure a proper reset.

CLOCK

The AD1170 requires a 12MHz clock for operation. This clock may be supplied by connecting the XTAL OUT and XTAL IN pins to a 12MHz crystal, along with two resistors and two capacitors as shown in Figure 5.

The user may also supply a 12MHz logic signal from an external source, such as may be available in the user's system. In this case, the external clock should be applied to the XTAL IN pin, and the XTAL OUT pin should remain unconnected.

POWERING THE AD1170

For best performance, the user should pay careful attention to proper power supply bypassing, as well as grounding. Analog common and digital common are not connected internal to the module, but must be connected externally. Figure 5 illustrates the proper connection of power and ground to the AD1170[1].

REFERENCE CONNECTIONS

The internal +5 volt reference of the AD1170 is brought out to Pin 21 of the module; for normal operation, it should be connected to the reference input (Pin 23).

An external reference voltage of from 4.5 to 5.5 volts may be applied to the reference input (Pin 23), and the reference output may remain unconnected. The data will be ratiometric to that reference. The input impedance of the reference input is approximately 16K ohms. The reference input is not dynamic; any external reference voltage must be an essentially static DC signal.

INTERFACING TO THE AD1170

The AD1170 contains an eight-bit microprocessor compatible interface structure, including control lines. It can be interfaced to any microprocessor-based system in either a memory mapped or I/O mapped mode, and occupies four successive bytes of read/write address space, as shown in Figure 6.[1]

	$\overline{CS}$	$\overline{RD}$	$\overline{WR}$	A1	A0	FUNCTION
	H	X	X	X	X	Device Not Selected
WRITE	L	H	L	H	H	(Unused)

WRITE	L	H	L	L	H	Parameter 1 Write
WRITE	L	H	L	L	L	Command Write
READ	L	L	H	H	H	High Data Read
READ	L	L	H	H	L	Mid Data Read
READ	L	L	H	L	H	Low Data Read
READ	L	L	H	L	L	Status Read

X = DON'T CARE

Figure 6. Control Functions

[1]Attempting to READ and WRITE at the same time ($\overline{RD}$ and $\overline{WR}$ set low) may alter the contents of the internal nonvolatile memory.

byte of the device image. Upon receipt of the command byte, the BUSY line is set low, indicating that command interpretation is in progress. The BUSY line returns high, following command interpretation and a command dependent execution time. This signals that the command execution has been completed, and another command may now be written. The logical inverse of the BUSY line is available in the STATUS byte for use in polling. See the section below about THE STATUS BYTE.

When the command requires one or two parameters, in addition to the command byte, they must be written into the second and third parameter bytes of the image *before* writing the command byte. This is because writing the command byte triggers the microprocessor to begin command interpretation.

Following the execution phase of any command, the CMD ERR bit in the STATUS byte will indicate acceptance or rejection of the command. When set, this bit indicates that there was a contextual or syntactic error in the command or parameters.

Conversions may be initiated either by bus command, or by a high to low transition of the EXT CC line[1]. Externally triggered conversions behave in the same way as bus triggered conversions, except that the BUSY line and the BUSY bit in the status word remain inactive; the end of execution of externally triggered conversions must be determined by examination of the DTA RDY line or the DTA RDY bit in the STATUS word.

THE STATUS BYTE

The lowest readable byte of the device image is the STATUS byte; it contains six bits of information about the current status of the AD1170. This byte may be examined by the host processor at any time. The individual bits in the status byte (see Figure 7) are assigned the following functions:

BIT0 The BUSY bit is an inverted version of the signal on Pin 7 of the module. When low, it indicates that the AD1170 is ready to receive a command. When high, it indicates that the AD1170 is busy executing the last command. Any commands loaded while the BUSY signal is high will be ignored.

BIT1 The DTA RDY bit (also available on Pin 10 of the module) goes high to indicate that the data from the most recent conversion is available in the LOW DATA, MID DATA, and HIGH DATA registers. This bit is cleared at the start of the next conversion. It may also be cleared by executing an EOI command.

BIT2 The DATA SAT bit is set by any conversion which is saturated, i.e., any conversion whose output data exceeds positive or negative full scale.

BIT3 The CMD ERR bit indicates that the most recently loaded command contained a contextual or syntactic error, or was not recognized. It is cleared when the next command is loaded.

BIT4 The INT bit (also available on Pin 11 of the module) goes high to indicate that the input signal is currently being integrated. It is used in multiplexed systems to determine when the input multiplexer may be switched.

BIT5 The PWRUP bit (also available on Pin 14 of the module) goes high when the module is powered up or when the RST command is executed. It remains high until device initialization is complete. This signal is used to indicate readiness of the converter after system initialization.

Figure 7. The Status Byte

OUTPUT DATA FORMAT

The AD1170 architecture allows a programmable data format independent of the integration time. The user may specify any resolution from 7 to 22 bits, and may specify either offset binary coding or two's complement coding. Programming the data format is accomplished via the use of the SDF command, using the format code described in the table in Figure 8 as the PARAMETER 1 value.

C_4	C_3	C_2	C_1	C_0	DATA FORMAT
H	X	X	X	X	Two's Complement
L	X	X	X	X	Offset Binary
X	H	H	H	H	22 Bits
X	H	H	H	L	21 Bits
X	H	H	L	H	20 Bits
X	H	H	L	L	19 Bits
X	H	L	H	H	18 Bits
X	H	L	H	L	17 Bits
X	H	L	L	H	16 Bits
X	H	L	L	L	15 Bits
X	L	H	H	H	14 Bits
X	L	H	H	L	13 Bits
X	L	H	L	H	12 Bits
X	L	H	L	L	11 Bits
X	L	L	H	H	10 Bits
X	L	L	H	L	9 Bits
X	L	L	L	H	8 Bits
X	L	L	L	L	7 Bits

X = DON'T CARE (C_7 C_6 C_5 = X FOR ALL DATA FORMATS)

Figure 8. Format Code

It should be noted that the AD1170 computes all data to 22 bit resolution. However, not all 22 bits are useable, since the differential performance is largely dependent upon factors such as integration period and calibration period. The SDF command simply serves to round off the result to the specified number of bits. The graph in Figure 4 can be used to estimate the amount of useable resolution achievable for a specified integration period and calibration period.

The output data is always right justified within the three output bytes (LOW DATA, MID DATA, and HIGH DATA). If two's complement format is selected, the MSB of the data is inverted and extended all the way to the top of the HIGH DATA byte. For example, if 16 bit two's complement format is selected, the data will appear in the LOW DATA and MID DATA bytes, and the MSB will be 0 for positive inputs.[2] The format is a nonvolatile parameter; whenever an SAVA command is executed, the current format will be saved to nonvolatile memory, and will become the default format upon powerup.

[1]The minimum duaration for $\overline{\text{EXT CC}}$ is one microsecond.

2Since the sign is extended all the way to the top of the uppermost byte, the HIGH DATA byte will be filled with the value of the MSB.

PROGRAMMING THE INTEGRATION PERIOD

The key parameter of any integrating A/D converter is the integration period. As shown in Figure 9, an integrating A/D converter provides maximum normal mode rejection at those frequencies which are integral multiples of 1/T(int), where T(int) is the integration period. The most common way to exploit this characteristic is to set the integration period equal to one period of the power line frequency so that ac hum will be rejected.

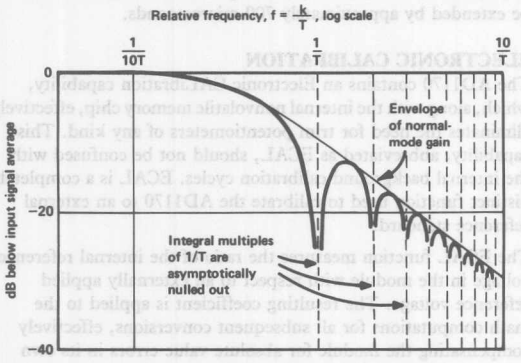

Figure 9. Normal Mode Rejection

The duration of the integration also affects the resulting resolution of the data; long integration times result in more usable resolution than do short integration periods.

The AD1170, unlike most dual slope converters, offers the user the capability of programming the integration time. This feature can be used to great advantage in systems design, since the integration time can be optimized for differing system conditions. For example, in systems whose inputs are severely polluted by 60Hz noise, the user may wish to program the AD1170 for a 100 millisecond integration time, which will result in excellent 60Hz normal mode rejection. In another application, a user may wish to scan a large number of channels rapidly, looking for gross input changes, then slow down in order to make a high resolution conversion before resuming rapid scanning.

The AD1170 offers the user a number of different ways to set the integration period. The simplest way is by using the SDI command to set the default integration period to one of seven preset periods (1ms, 10ms, 16.66ms, 20ms, 100ms, 166.66ms, 300ms). The first two preset periods offer fairly rapid scanning at reduced resolution; the other five represent American and European line voltage standards or multiples thereof. For single conversions without altering the default integration time, the CNVP command may be used, which also allows the selection of one of these seven preset periods. These preset periods and their corresponding codes are listed in the table of Figure 10.

Another way in which the integration period may be programmed is via the EIS command, which allows the user to load the externally definable period register with a binary value[1] proportional to the desired integration period. Using this technique, the user may specify any period from one millisecond to 350 milliseconds (with 200 microsecond accuracy). Access to this user definable period is via the SDI or CNVP commands; the last entry in Figure 10 is used to select the period defined by the EIS or ELS command.

C_2	C_1	C_0	INTEGRATION TIME	NOTES
L	L	L	1 Millisecond	
L	L	H	10 Milliseconds	
L	H	L	16.667 Milliseconds	1 cycle @ 60Hz
L	H	H	20 Milliseconds	1 cycle @ 50Hz
H	L	L	100 Milliseconds	50/60Hz
H	L	H	166.67 Milliseconds	10 cycles @ 60Hz
H	H	L	300 Milliseconds	50/60Hz
H	H	H	(See Note)	

NOTE
This code is used for externally loaded integration times (defined with the EIS Command) or externally measured times (from the ELS Command). The value can be anywhere from 1 Millisecond to 350 Milliseconds.

Figure 10. Preset Integration Periods

The third way to set the integration period is via the external line sampling feature, using the ELS command. This command samples the period of the logic signal presented to the ELS input pin (Pin 12), and sets the externally definable period register accordingly. This feature is most useful in environments with fluctuating line frequencies. By executing an occasional ELS command, the converter effectively "tracks" the line frequency. To use this feature, a clean, bounce free logic representation of the line frequency must be present at the ELS input during the execution of the ELS command. Once having performed the ELS command, the measured integration time may be selected using the SDI or CNVP commands along with the (HHH) code from the table in Figure 10[2].

It should be noted that the actual integration period used in the measurement process is accurate to about ±200μs, due to the limitations of the charge balancing converter. This is adequate, however, for greater than 50dB of normal mode rejection at 60Hz when using an integration period of 1/60 second. Even greater normal mode rejection may be obtained when the integration period is a multiple of the line frequency period.

CONTROLLING THE CALIBRATION CYCLE

The AD1170 achieves its excellent span and offset stability by calibrating itself against its internal reference voltages. The user can control the frequency of occurrence for calibration cycles and their duration.

The duration of the calibration cycle is an important parameter, because it affects the accuracy of the calibration cycle itself. Errors in the calibration cycle appear in the output data as instantaneous offset and span errors. If automatic "background" calibration is enabled, these errors effectively appear as noise. Just as in the case of input conversions, longer calibration times result in more accuracy and less noise.

Of course there may be system applications where there simply isn't sufficient time to perform a long calibration cycle. For this reason, the AD1170 offers the user the ability to specify the calibration period, using the SDC command.

The argument for the SDC command is the same three-bit code as is used for the SDI and CNVP commands. The reason for

[1]See the section titled "The AD1170 Command Set" for the formula used to compute the proper binary value.

[2]Caution is advised; if no signal is present at the ELS input when the ELS command is executed, or if the signal is not within acceptable frequency limits, the module may "hang" and require a hardware reset to continue operation.

this is that each calibration cycle consists essentially of two ordinary conversion cycles, performed upon the internal zero and span references. For example, if an SDC command with an argument of 3 is executed, the default calibration time will then be approximately 49 milliseconds (two conversions of 20 milliseconds plus approximately 9 milliseconds for the internal mathematics).

The user may also disable or enable background calibration. In systems where the AD1170 may be periodically idle, i.e., not performing input conversions, background calibration is a good choice. This mode is enabled with the CALEN command and will cause the AD1170 to continually initiate an internal calibration cycle whenever the converter is otherwise unoccupied. Any conversion commands received during a cal cycle will cause that cal cycle to be aborted in favor of the input conversion, thereby giving the user priority over calibration. This mode of operation is automatic and transparent.

The CALDI instruction is used to disable background calibration. When this instruction is executed, the converter will be completely idle between convert commands, and calibration cycles will only occur when invoked by the SCAL command. This mode of operation is best when the user would like to perform input conversions at the maximum rate, and/or when the system affords a specific convenient time to perform calibration.

There are no hard and fast rules about the best way to apply all of this flexibility, but best performance will be obtained if the following points are observed:

- Consult the chart in Figure 4 to determine the minimum effective calibration period for use with a desired integration period.
- Don't use automatic background calibration unless your system will allow the converter enough uninterrupted time to perform at least one calibration cycle. For example, if you are using a calibration period code of 3, your system must periodically allow at least 49 milliseconds without a convert command or calibration will not occur.
- Remember that the purpose of the calibration cycle is to cancel the intrinsic drift of the charge balancing converter within the AD1170 itself. If the converter is in a stable environment, calibration may be done less frequently. The best possible performance will be achieved in stable ambient temperatures, where calibration is manually invoked by the system at relatively long intervals, using the longest allowable calibration time.
- Very short calibration times, although allowed by the AD1170 firmware, are not especially useful because they introduce more error than they compensate. The only useful purpose of very short calibration times is in systems which are operating in rapidly changing ambient temperatures, and then only for relatively low resolution conversions.

COMPENSATION OF EXTERNAL OFFSETS

An electronic "null" feature compensates for offset errors of signal conditioning stages preceding the AD1170.

The null feature comprises three commands: NULL measures the input signal (using the current integration time) and stores it in internal RAM; NULEN subtracts the measured value from all subsequent conversions; NULDI cancels the NULEN command's effect.

The sum of the offset value plus the full-scale input should be less than the ±6 volts linear input range of the AD1170. The offset value to be nulled should ideally be no more than a few hundred millivolts in amplitude.

The NULL command does not need to be executed every time the AD1170 is powered up. Since the value measured by the NULL command is saved and restored by the SAVA and RESA commands, the value of the null will be the one saved during the last SAVA command. Execute a NULL command only when a new null measurement is desired.

When NULEN is in effect, the length of each conversion will be extended by approximately 700 microseconds.

ELECTRONIC CALIBRATION

The AD1170 contains an Electronic CALibration capability, which, along with the internal nonvolatile memory chip, effectively eliminates the need for trim potentiometers of any kind. This capability, abbreviated as ECAL, should not be confused with the internal background calibration cycles. ECAL is a completely distinct function used to calibrate the AD1170 to an external reference standard.

The ECAL function measures the ratio of the internal reference voltage in the module with respect to an externally applied reference voltage. The resulting coefficient is applied to the math computations for all subsequent conversions, effectively compensating the module for absolute value errors in its own reference. The ratio is stored in random access memory until the user invokes a SAVA command, which will save this coefficient (along with the other nonvolatile parameters) in the nonvolatile memory chip. When the module is powered up, the previously saved coefficient is recalled from nonvolatile memory and stored in random access memory.

In order to use the ECAL command, the input to the AD1170 must first be presented with an external +5 volt reference standard such as is usually found in many calibration labs. The ECAL command may then be invoked; the external reference voltage must remain at the input until command execution is complete. If the calibration is to be made nonvolatile, a SAVA command must then be invoked.[1]

ECAL may also be used as a means of making limited ratiometric measurements. For example, in some applications, it may be useful to be able to measure the output of some transducer with respect to its excitation; if the excitation can be scaled to the range of 4.5 to 5.5 volts, then it can be used as an excitation for the ECAL process. Having digitized the excitation, all subsequent conversions will be ratioed to the ECAL value. For example, if an ECAL procedure is performed upon a 4.5 volt source, and the converter subsequently digitizes a 2.25 volt signal, the converter output will be half of full scale, or 11000... (assuming offset binary coding). The converter can be restored to absolute calibration by executing a RESA command, which will restore the last nonvolatile ECAL coefficient to random access memory.

The user is cautioned that the nonvolatile memory used in the AD1170 has a finite endurance of 1000 write cycles minimum. Assuming that the AD1170 is calibrated weekly, this implies a device life span of greater than 19 years. Less frequent calibrations mean a proportionately longer life span. This means ECAL may be performed any number of times, but the user should limit the number of SAVA commands in order to extend the life span of the nonvolatile memory.

[1]Since the SAVA command saves all nonvolatile parameters, the user should be sure that the other default parameters, such as integration time and data format, are set to their desired values before SAVA is invoked.

NONVOLATILE MEMORY

The internal nonvolatile memory in the AD1170 is used to store the various nonvolatile parameters associated with A/D operation (for example, the integration period, data format, ECAL coefficient, etc.).

In addition, eight 16-bit words of the nonvolatile memory are made available to the user for general purpose use. They may be accessed using the RDNV and WRNV commands. Because the nonvolatile memory is specified for a finite endurance of 1000 write cycles minimum, it is best used for data which does not regularly need to change, such as configuration information or system calibration parameters.

FACTORY DEFAULT SETTINGS

The AD1170 is calibrated at the factory; the factory default settings are:

Format: 16-bit, offset binary
Default T(int): 16.667 milliseconds (code 2)
Default T(cal): 100 milliseconds (code 4)

THE AD1170 COMMAND SET

The AD1170 command code set includes 20 different functions. Some of the commands require no parameters, while others require one or two parameters which must be loaded into the PARAMETER 1 and PARAMETER 2 registers prior to loading the command register. Some commands (for example, CNVP) have their option parameter embedded in the lowest three bits of the command itself.

The execution time for any command depends on the command. Figure 11 is a synopsis of the available commands, as well as estimates of their execution times.

Each of the commands described below is preceded by an opcode name, along with the digital code (in binary).

CALEN 10110000

CALEN (CALibration ENable) enables automatic background calibration cycling. In this mode, background calibration cycles are executed automatically whenever the AD1170 is not otherwise occupied. If a command is received during a calibration cycle, that cycle will be aborted and the command will be executed.

CALDI 10111000

CALDI (CALibration DIsable) disables automatic background calibration. After executing this command, the AD1170 will be completely idle between commands. While in this state, a single calibration cycle may be invoked with the SCAL command.

CNV 00001000

CNV (CoNVert) causes a single conversion to be performed, using the current default integration time and data format.

CNVP $00010C_2C_1C_0$

CNVP (CoNVert using specific Preset time) causes a single conversion to be performed, using one of the eight preset integration times as listed in Figure 10. The default integration time is not changed. The three bit code for the desired integration time is embedded in the lowest three bits of the command code.

ECAL 00011000

ECAL (Electronic CALibration) causes an electronic calibration cycle to be performed. An external +5 volt reference voltage must be presented to the input before this command is executed, and the input must remain stable until the end of command execution is signaled by the BUSY line or the BUSY bit in the status word. The calibration data computed by this command is applied to all subsequent conversions, but is not made nonvolatile until a SAVA command is performed.

MNEMONIC	FUNCTIONAL DESCRIPTION	EXECUTION TIME (APPROX)
CNV	Perform a Single Conversion Using the Default Integration Time	T(int) + 3ms
CNVP	Perform a Single Conversion Using the Specified Integration Time	T(int) + 3ms
ELS	Measure Period of Signal at the ELS Input	2 × T(int) + 20ms
ECAL	Perform Electronic CALibration Routine	1.5 seconds
SDI	Set Default Integration Time for Input Measurements	150µs
SDC	Set Default Calibration Period	160µs
SDF	Set Default Data Format	140µs
RESA	Restore All Nonvolatile Parameters from Memory	2.3ms
SAVA	Save All Nonvolatile Parameters to Memory	150ms
WRNV	Write a Word to the User EEPROM Area	22ms
RDNV	Read a Word from the User EEPROM Area	600µs
EOI	Clear the Data Ready Flag	260µs
SCAL	Perform a Single Cal Cycle	2 × T(cal) + 9ms
CALEN	Enable Background Calibration	300µs
CALDI	Disable Background Calibration	310µs
EIS	Set Integration Time to Arbitrary Value	130µs
RST	Reset AD1170 to Power Up Conditions	210ms
NULL	Measure the Offset Voltage Value at the AD1170 Input and Store	T(int) + 3ms
NULEN	Subtract NULL Measured Value from All Subsequent Conversions	250µs
NULDI	Cancel the Effect of the NULEN Command	250µs

Figure 11. Synopsis of Commands

EOI 10001000

EOI (End Of Interrupt) clears the DTA RDY bit in the status byte, as well as the DTA RDY line (Pin 10). It is provided as a means of clearing the interrupt source in systems which use an interrupt upon data ready.

ELS 00100000

ELS (External Line Sample) measures the period of the logic signal applied to the ELS input (Pin 12)[1]. This period is loaded into the register associated with the last entry of the table in Figure 10. Input conversions using this measurement as the integration period may be performed by invoking a CNVP command, or by setting the default integration period with the SDI command. This command is intended for use in environments with varying line power frequency; periodically invoking this command allows effective tracking for improved normal mode rejection.

EIS 00101000

EIS (External Integration Set) is used to establish an arbitrary integration period from 1 millisecond to 350 milliseconds. To use this command, first load the PARAMETER 1 and PARAMETER 2 registers with the 16-bit binary number N, which is calculated using the following expression:

$$N = 2^{16} - T(int)/21.333E\text{-}6$$

After the low and high bytes representing N are loaded into the PARAMETER 1 and PARAMETER 2 registers respectively, execute the EIS command. Once this command is executed, the externally loaded integration time can be used via the CNVP or SDI commands.

RESA 01101000

RESA (REStore All) restores all configuration parameters (default integration time, default calibration time, data format, EIS/ELS period, NULL value and electronic calibration data) from nonvolatile memory. After executing this function, all parameters will be restored to their last value as saved by the SAVA command.

SAVA 01001000

SAVA (SAVe All) saves all programmable attributes (default integration time, default calibration time, data format, EIS/ELS period, NULL value and electronic calibration data) into nonvolatile memory.

SDI $00111C_2C_1C_0$

SDI (Set Default Integration time) sets the default integration time to one of the eight preset times listed in Figure 10. The three-bit code for the desired integration time is embedded in the lowest three bits of the command code.

SDF 00110000

SDF (Set Default Format) sets the default data format according to the five bit code loaded into the PARAMETER 1 register prior to execution of this command. The table in Figure 8 illustrates the construction of the five bit code according to the desired data format and resolution.

SCAL 11000000

SCAL (Single CALibration) performs a single background calibration cycle. This command is intended for use when automatic background calibration has been disabled via the CALDI command.

SDC $01000C_2C_1C_0$

SDC (Set Default Calibration time) sets the default calibration time (Tcal) according to the three bit code embedded in the lowest three bits of the command. The calibration times are shown in Figure 10. Note that the actual duration of a calibration cycle is approximately $2 \times T(cal) + 9$ milliseconds.

WRNV $10011A_2A_1A_0$

WRNV (WRite NonVolatile) writes the user supplied data, in the PARAMETER 1 and PARAMETER 2 registers, into the user accessible area of the AD1170's nonvolatile memory. Eight words of this memory are available, and are addressed by the lowest three bits of the command.

RDNV $10100A_2A_1A_0$

RDNV (ReaD NonVolatile) reads one word from the user accessible portion of the nonvolatile memory within the AD1170, and places the data into the LOW DATA and MID DATA registers for retrieval by the user. The address of the desired word is embedded into the lowest three bits of the command.

RST 10010000

RST (ReSeT) is effectively equivalent to a hardware reset of the AD1170. After executing this command, all nonvolatile parameters (including the ECAL coefficient, the default integration and calibration periods, EIS/ELS period, NULL value and the default format) will be restored to their last saved values, automatic calibration will be enabled, and NULL will be disabled.

NULL 01110000

NULL measures the input signal (using the curent integration time value) and stores the measurement in internal RAM. It allows the user to establish the value of offset voltage at the input and subtract that offset from subsequent conversions through the execution of the NULEN command. The user must insure that the sum of the offset value plus the full scale input is less than the ± 6 volts linear input range of the AD1170. Ideally the offset value to be nulled should be no more than a few hundred millivolts in amplitude. The value measured by the NULL command is saved and restored by the SAVA and RESA commands – maintaining this value through subsequent powerups. The NULL command need only be invoked when a new null measurement is desired.

NULEN 01111000

NULEN (NULl ENable) subtracts the value, measured and stored by the last NULL command, from all subsequent conversions. When NULEN is in effect, each conversion's length will be extended by approximately 700 microseconds.

NULDI 10000000

NULDI (NULl DIsable) cancels the effect of the NULEN command.

[1]This logic signal should be a TTL or CMOS compatible continuous waveform. It need not be symmetrical, but the HIGH or LOW time should not be less than 25 microseconds.

IBM PC INTERFACE

Figure 12 is an example of an AD1170/IBM interface suitable for the IBM PC or XT personal computers. In this case, the AD1170 is interfaced in the I/O space; the DIP switch controls the specific location of the AD1170 within the available address space.

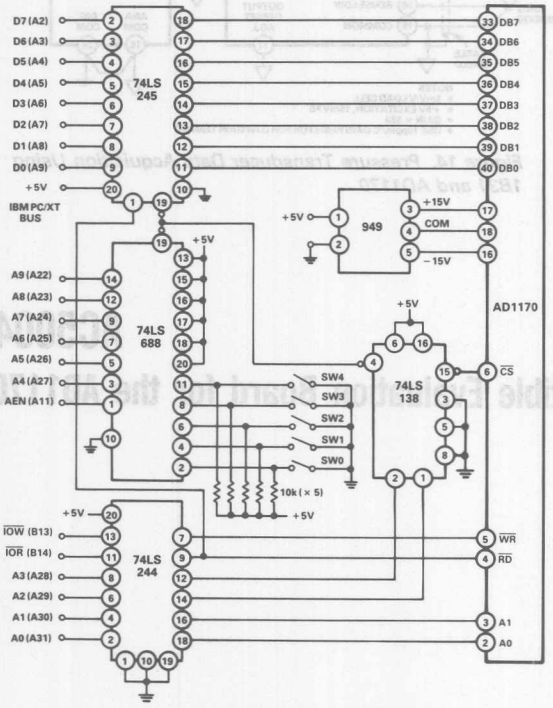

Figure 12. IBM PC/XT to AD1170 Interface

INTERFACING TO AN 8051 MICROCONTROLLER

Figure 13 shows how an AD1170 may be interfaced to an 8051 microcontroller using a technique commonly called "byte banging", where the control lines and data bus of a device are manipulated under firmware control. This "byte banging" technique can be adapted to most microprocessors and is useful in situations where a conventional bus structure is either nonexistent or unavailable for use.[1]

The AD1170's data bus is connected to the 8051 using I/O lines P2.0 through P2.7. The address lines A0 and A1 are connected to I/O lines P1.0 and P1.1 respectively. The RD/ and WR/ lines are connected to P1.2 and P1.3. The CS/ line of the AD1170 is grounded when it is the only device connected to the 8051, but multiple AD1170s could easily be connected in the same way if each CS/ line were separately controlled.

[1]Note that the 8051 microcontroller *does* contain a conventional bus structure; the "byte banging" interface shown here is presented as an example of an alternative technique.

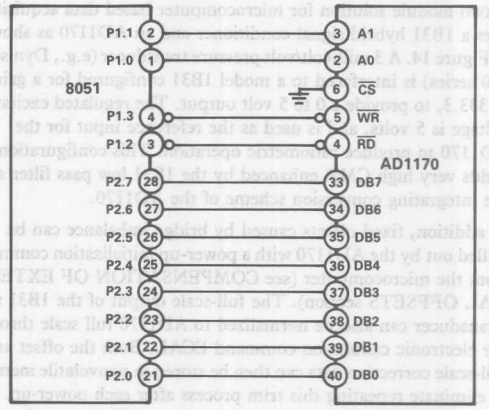

Figure 13. Simple 8051 to AD1170 Interface

To initialize the interface, first write "1"s to the port pins connected to the data bus and the RD/ and WR/ control lines. This puts the 8051 I/O lines into a lightly "pulled up" state, simulating a tri-stated condition on the bus to insure that neither RD/ or WR/ are selected:

```
INIT:   SETB  P1.2      ;DISABLE RD/
        SETB  P1.3      ;AND WR/
                        ;
        MOV   P2, #OFFH ;SET P2 TO ALL ONES
```

To write a command to the AD1170, first set the state of the P1.1 and P1.0 lines for the address corresponding to the byte to be written to. Set the P2 port to the command data, then strobe the WR/ line by first clearing the P1.3 line and then setting it:

```
WRCMD:  CLR   P1.0      ;FIRST CLEAR A0 AND A1
        CLR   P1.1      ;TO POINT TO CMD BYTE
                        ;
        MOV   P2, #CNV  ;CNV IS THE OPCODE FOR
                        ;A SINGLE CONVERSION
                        ;
        CLR   P1.3      ;STROBE THE WR/ LINE
        SETB  P1.3      ;ONE TIME
                        ;
        MOV   P2, #OFFH ;CLEAR DATA BUS TO
                        ;ALL ONES
```

To read a byte from the AD1170, first set the P1.0 and P1.1 lines to point to the address of the byte desired. Bring the RD/ line low, reading the contents of P2. Return the RD/ line high:

```
RDSTAT: CLR   P1.0      ;POINT TO STATUS BYTE
        CLR   P1.1      ;
                        ;
        CLR   P1.2      ;BRING RD/ LINE LOW
        MOV   A,P2      ;READ CONTENTS OF BUS
        SETB  P1.2      ;RESTORE RD/ LINE HIGH
```

in Figure 14. A 3 millivolt/volt pressure transducer (e.g., Dynisco's 800 series) is interfaced to a model 1B31 configured for a gain of 333.3, to provide a 0 to 5 volt output. The regulated excitation voltage is 5 volts, and is used as the reference input for the AD1170 to produce ratiometric operation. This configuration yields very high CMR enhanced by the 1B31 low pass filter and the integrating conversion scheme of the AD1170.

In addition, fixed offsets caused by bridge imbalance can be nulled out by the AD1170 with a power-up initialization command from the microcomputer (see COMPENSATION OF EXTERNAL OFFSETS section). The full-scale output of the 1B31 and Transducer can also be normalized to AD1170 full scale through the electronic calibration command ECAL. Both the offset and full-scale correction data can then be stored in nonvolatile memory to eliminate repeating this trim process after each power-up. The AD1170 eliminates a potentiometer or software overhead which might otherwise be needed for these functions.

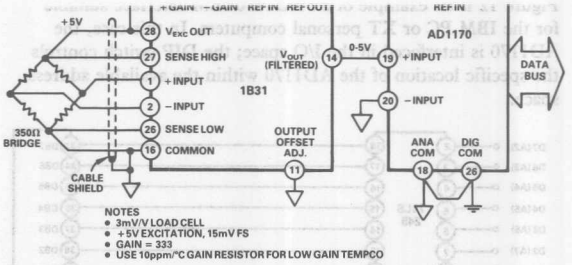

Figure 14. Pressure Transducer Data Acquisition Using 1B31 and AD1170

AC5004

. . . an IBM PC/XT/AT Compatible Evaluation Board for the AD1170

FEATURES

Compatible to the IBM PC/XT/AT or Equivalent
Menu-Driven Demonstration Software
Input Mating Connector
Full Documentation
Example Listings of BASIC Programs
Schematic
Assembly Drawing
Complete Set of Tools to Evaluate an AD1170 A/D Converter

GENERAL DESCRIPTION

The AC5004 was designed as a support tool to enable the user to easily and quickly evaluate Analog Devices' AD1170 high-resolution programmable integrating A/D converter. The AD1170 is inserted directly into an AC5004 board which is designed to plug into the backplane of an IBM PC/XT/AT. Thus, armed with an IBM PC, an AD1170, and an AC5004 evaluation board, the user is fully prepared to examine the operation of the AD1170.

A User's Manual provides all the information required to put the AC5004/AD1170 evaluation process into operation. In the manual are full descriptions of the AC5004 memory address and power source selection jumpers as well as a schematic documenting the interface of the AD1170 to a computer bus.

The package also contains a comprehensive demonstration program written in BASIC that completely exercises all the functions of the AD1170. The AC5004 is an accessory that will make readily available to the user all the tools needed to comprehensively test the AD1170.

PRODUCT HIGHLIGHTS

1. AC5004 plugs directly into IBM PC/XT/AT or compatibles. Standard short slot card size (5 7/8″ × 5″ × 1″).
2. The AC5004 enables the user to evaluate the AD1170 high-resolution, programmable, integrating A/D converter without having to build a bread-board or prototype.
3. The evaluation boards come complete with software and programming examples designed to exercise all of the AD1170's functions.
4. AC5004 schematic and assembly drawings are provided to be used as examples of how to interface the AD1170 to a microprocessor bus.

Please note:
Order *AC5004* (does not include AD1170).

Complete, High Speed 16-Bit A/D Converters

AD1376/AD1377

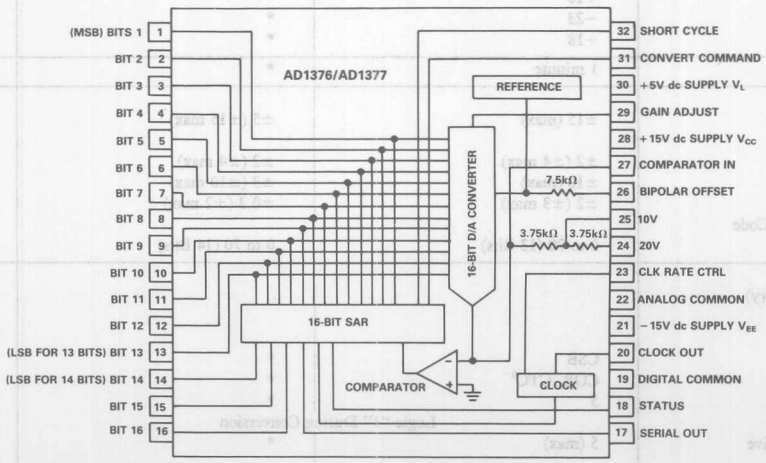
FEATURES

Complete 16-Bit Converters with Reference and Clock
±0.003% Maximum Nonlinearity
No Missing Codes to 14 Bits over Temperature
Fast Conversion
17 μs to 16 Bits (AD1376)
10 μs to 16 Bits (AD1377)
Short Cycle Capability
Adjustable Clock Rate
Parallel and Serial Outputs
Low Power: 645 mW Typical (AD1376)
585 mW Typical (AD1377)
Industry Standard Pin Out

PRODUCT DESCRIPTION

The AD1376 and AD1377 are high resolution, 16-bit analog-to-digital converters with internal reference, clock and laser-trimmed thin-film applications resistors. They are packaged in compact 32-pin, ceramic seam sealed (hermetic) dual-in-line packages (DIPs). Thin-film scaling resistors provide bipolar input ranges of ±2.5 V, ±5 V, ±10 V and unipolar input ranges of 0 to +5 V, 0 to +10 V, and 0 to +20 V.

Digital output data is provided in parallel and serial form with corresponding Clock and Status outputs. All digital inputs and outputs are TTL compatible.



APPLICATIONS

The AD1376 and AD1377 are excellent for use in high resolution applications requiring moderate speed and high accuracy or stability over commercial (0°C to +70°C) temperature ranges. For extended temperature ranges, the pin compatible AD1378 is recommended. Typical applications include medical and analytic instrumentation, precision measurement for industrial robotics, automatic test equipment (ATE), and multichannel data acquisition systems, servo control systems, or anywhere wide dynamic range is required. A proprietary monolithic DAC and laser-trimmed thin-film resistors guarantee a maximum nonlinearity of ±0.003% (1/2 LSB_{14}.) The converters may be short cycled to achieve faster conversion times—15 μs to 14 bits for the AD1376, or 8 μs to 14 bits for the AD1377.

PRODUCT HIGHLIGHTS

1. The AD1376 and AD1377 provide 16-bit resolution with a maximum linearity error of ±0.003% (1/2 LSB_{14}) at +25°C.
2. AD1376 conversion time is 14 μs (typical) short cycled to 14 bits, and 16 μs to 16 bits.
3. AD1377 conversion time is 8 μs (typical) short cycled to 14 bits, and 9 μs to 16 bits.
4. Two binary codes are available on the digital output. They are CSB (Complementary Straight Binary) for unipolar input voltage ranges and COB (Complementary Offset Binary) for bipolar input ranges. Complementary Twos Complement (CTC) coding may be obtained by inverting Pin 1 (MSB).
5. The AD1376 and AD1377 include internal reference and clock, with external clock rate adjust pin, and serial and parallel digital outputs.

FUNCTIONAL BLOCK DIAGRAM

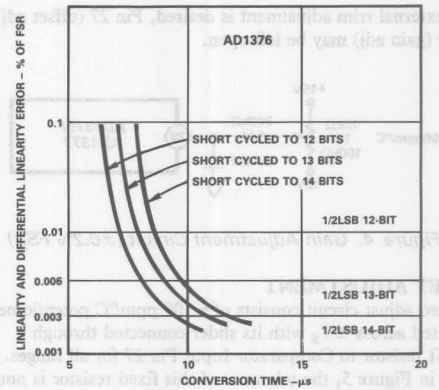

Figure 2. AD1376 Nonlinearity vs. Conversion Time

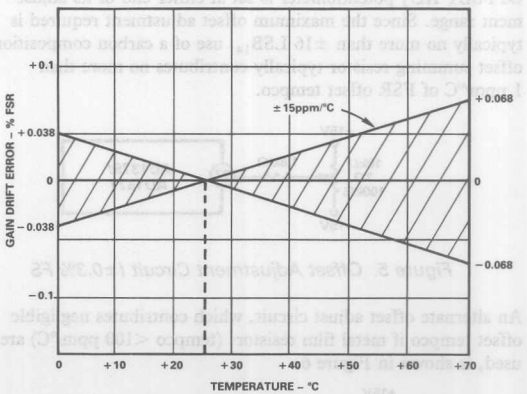

Figure 3. Gain Drift Error vs. Temperature

DESCRIPTION OF OPERATION

On receipt of a CONVERT START command, the AD1376 or AD1377 converts the voltage at its analog input into an equivalent 16-bit binary number. This conversion is accomplished as follows: the 16-bit successive-approximation register (SAR) has its 16-bit outputs connected both to the device bit output pins and to the corresponding bit inputs of the feedback DAC. The analog input is successively compared to the feedback DAC output, one bit at a time (MSB first, LSB last). The decision to keep or reject each bit is then made at the completion of each bit comparison period, depending on the state of the comparator at that time.

GAIN ADJUSTMENT

The gain adjust circuit consists of a 100 ppm/°C potentiometer connected across $\pm V_S$ with its slider connected through a 300 kΩ resistor to the gain adjust Pin 29 as shown in Figure 4.

If no external trim adjustment is desired, Pin 27 (offset adj) and Pin 29 (gain adj) may be left open.

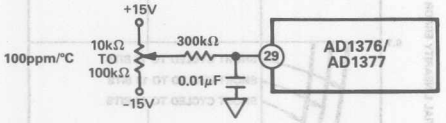

Figure 4. Gain Adjustment Circuit (±0.2% FSR)

OFFSET ADJUSTMENT

The zero adjust circuit consists of a 100 ppm/°C potentiometer connected across $\pm V_S$ with its slider connected through a 1.8 MΩ resistor to Comparator Input Pin 27 for all ranges. As shown in Figure 5, the tolerance of this fixed resistor is not critical, and a carbon composition type is generally adequate. Using a carbon composition resistor having a −1200 ppm/°C tempco contributes a worst-case offset tempco of 32 LSB_{14} × 61 ppm/LSB_{14} × 1200 ppm/°C = 2.3 ppm/°C of FSR, if the OFFSET ADJ potentiometer is set at either end of its adjustment range. Since the maximum offset adjustment required is typically no more than ±16 LSB_{14}, use of a carbon composition offset summing resistor typically contributes no more than 1 ppm/°C of FSR offset tempco.

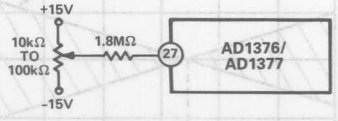

Figure 5. Offset Adjustment Circuit (±0.3% FS

An alternate offset adjust circuit, which contributes negligible offset tempco if metal film resistors (tempco <100 ppm/°C) are used, is shown in Figure 6.

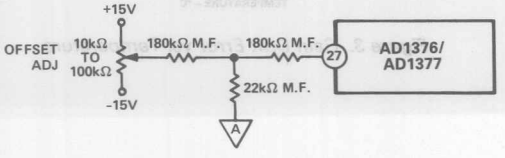

Figure 6. Low Tempco Zero Adjustment Circuit

In either adjust circuit, the fixed resistor connected to Pin 27 should be located close to this pin to keep the pin connection runs short. Comparator Input Pin 27 is quite sensitive to external noise pick-up and should be guarded by analog common.

TIMING

The timing diagram is shown in Figure 7. Receipt of a CONVERT START signal sets the STATUS flag, indicating conversion in progress. This, in turn, removes the inhibit applied to the gated clock, permitting it to run through 17 cycles. All the SAR parallel bits, STATUS flip-flops, and the gated clock inhibit signal are initialized on the trailing edge of the CONVERT START signal. At time t_0, B_1 is reset and B_2 – B_{16} are set unconditionally. At t_1 the Bit 1 decision is made (keep) and Bit 2 is reset unconditionally. This sequence continues until the Bit 16 (LSB) decision (keep) is made at t_{16}. The STATUS flag is reset, indicating that the conversion is complete and that the parallel output data is valid. Resetting the STATUS flag restores the gated clock inhibit signal, forcing the clock output to the low Logic "0" state. Note that the clock remains low until the next conversion.

Corresponding parallel data bits become valid on the same positive-going clock edge.

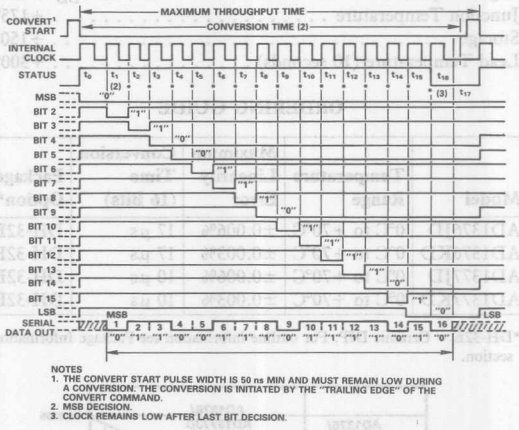

Figure 7. Timing Diagram (Binary Code 0110011101111010)

DIGITAL OUTPUT DATA

Both parallel and serial data from TTL storage registers is in negative true form (Logic "1" = 0 V and Logic "0" = 2.4 V). Parallel data output coding is complementary binary for unipolar ranges and complementary offset binary for bipolar ranges. Parallel data becomes valid at least 20 ns before the STATUS flag returns to Logic "0", permitting parallel data transfer to be clocked on the "1" to "0" transition of the STATUS flag (see Figure 8).

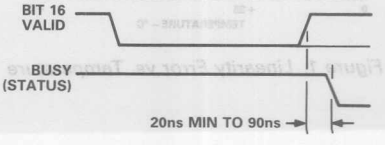

Figure 8. LSB Valid to Status Low

Serial data coding is complementary binary for unipolar input ranges and complementary offset binary for bipolar input ranges. Serial output is by bit (MSB first, LSB last) in NRZ (nonreturn-to-zero) format. Serial and parallel data outputs change state on positive-going clock edges. Serial data is guaranteed valid 120 ns after the rising clock edges, permitting serial data to be clocked directly into a receiving register on the negative-going clock edges as shown in Figure 9. There are 17 negative-going clock edges in the complete 16-bit conversion cycle. The first negative edge shifts an invalid bit into the register, which is shifted out on the last negative-going clock edge.

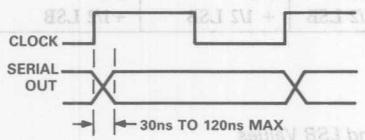

Figure 9. Clock High to Serial Out Valid

All serial data bits will have been correctly transferred and be in the receiving shift register locations shown at the completion of the conversion period.

Short Cycle Input: A Short Cycle Input, Pin 32, permits the timing cycle shown in Figure 7 to be terminated after any number of desired bits has been converted, permitting somewhat shorter conversion times in applications not requiring full 16-bit resolution. When 10-bit resolution is desired, Pin 32 is connected to Bit 11 output Pin 11. The conversion cycle then terminates and the STATUS flag resets after the Bit 10 decision (timing diagram of Figure 7). Short cycle connections and associated 8-, 10-, 12-, 13-, 14-, and 15-bit conversion times are summarized in Table I, for a 1.6 MHz clock (AD1377) or 933 kHz clock (AD1376).

INPUT SCALING

The ADC inputs should be scaled as close to the maximum input signal range as possible in order to utilize the maximum signal resolution of the A/D converter. Connect the input signal as shown in Table II. See Figure 10 for circuit details.

Table I. Short Cycle Connections

Resolution Bits	Resolution (% FSR)	Maximum Conversion Time–μs (AD1377)	Maximum Conversion Time–μs (AD1376)	Status Flag Reset	Connect Short Cycle Pin 32 to Pin:
16	0.0015	10	17.1	t_{16}	N/C (Open)
15	0.003	9.4	16.1	t_{15}	16
14	0.006	8.7	15.0	t_{14}	15
13	0.012	8.1	13.9	t_{13}	14
12	0.024	7.5	12.9	t_{12}	13
10	0.100	6.3	10.7	t_{10}	11
8	0.390	5.0	8.6	t_{8}	9

Table II. Input Scaling Connections

Input Signal Line	Output Code	Connect Pin 26 to Pin	Connect Pin 24 to	Connect Input Signal to
±10 V	COB	27	Input Signal	24
±5 V	COB	27	Open	25
±2.5 V	COB	27	Pin 27	25

	n = 14	1.22 mV	0.61 mV	0.31 mV	0.61 mV	0.31 mV
	n = 15	0.61 mV	0.31 mV	0.15 mV	0.31 mV	0.15 mV

NOTES
*COB = Complementary Offset Binary.
**CTC = Complementary Twos Complement — achieved by using an inverter to complement the most significant bit to product ($\overline{MSB}$).
***CSB = Complementary Straight Binary.

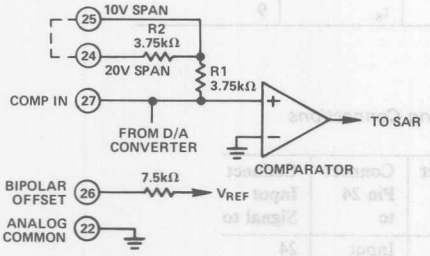

Figure 10. Input Scaling Circuit

Zero is now calibrated. Set analog input to +FSR − 2 LSB = + 9.99878 V. Adjust Gain for 00000000000001 digital output code; full scale (Gain) is now calibrated. Half scale calibration check: set analog input to +5.00000 V; digital output code should be 01111111111111.

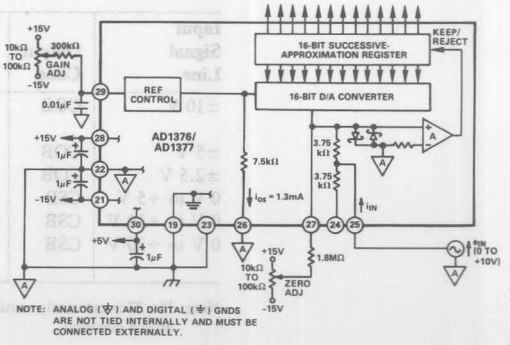

Figure 11. Analog and Power Connections for Unipolar 0 V to +10 V Input Range

CALIBRATION

(14-Bit Resolution Examples)

External ZERO ADJ and GAIN ADJ potentiometers, connected as shown in Figures 11 and 12, are used for device calibration. To prevent interaction of these two adjustments, Zero is always adjusted first and then Gain. Zero is adjusted with the analog input near the most negative end of the analog range (0 for unipolar and −FS for bipolar input ranges). Gain is adjusted with the analog input near the most positive end of the analog range.

0 V to + 10 V Range: Set analog input to + 1 LSB_{14} = 0.00061 V. Adjust Zero for digital output = 11111111111110.

−10 V to +10 V Range: Set analog input to −9.99878 V; adjust zero for 1111111111110 digital output (complementary offset binary) code. Set analog input to 9.99756 V; adjust Gain for 00000000000001 digital output (complementary offset binary) code. Half scale calibration check: set analog input to 0.00000 V; digital output (complementary offset binary) code should be 01111111111111.

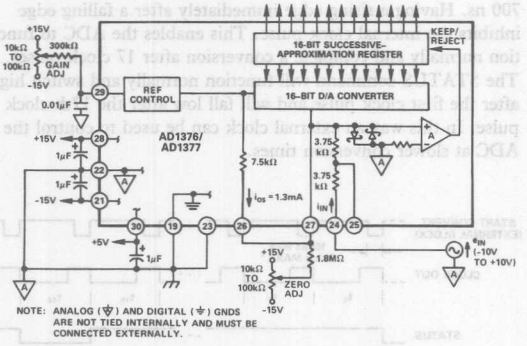

Figure 12. Analog and Power Connections for Bipolar +10 V to +10 V Input Range

Other Ranges: Representative digital coding for 0 V to +10 V and −10 V to +10 V ranges is given above. Coding relationships and calibration points for 0 V to +5 V, −2.5 V to +2.5 V and −5 V to +5 V ranges can be found by halving proportionally the corresponding code equivalents listed for the 0 V to +10 V and −10 V to +10 V ranges, respectively, as indicated in Table III.

Zero and full-scale calibration can be accomplished to a precision of approximately ±1/2 LSB using the static adjustment procedure described above. By summing a small sine or triangular wave voltage with the signal applied to the analog input, the output can be cycled through each of the calibration codes of interest to more accurately determine the center (or end points) of each discrete quantization level. A detailed description of this dynamic calibration technique is presented in *Analog-Digital Conversion Handbook* , edited by D. H. Sheingold, Prentice-Hall, Inc., 1986.

GROUNDING, DECOUPLING AND LAYOUT CONSIDERATIONS

Many data-acquisition components have two or more ground pins which are not connected together within the device. These "grounds" are usually referred to as the Logic Power Return, Analog Common (Analog Power Return) and Analog Signal Ground. These grounds (Pins 19 and 22) must be tied together at one point for the ADC as close as possible to the converter. Ideally, a single solid analog ground plane under the converter would be desirable. Current flows through the wires and etch stripes of the circuit cards, and since these paths have resistance and inductance, hundreds of millivolts can be generated between the system analog ground point and the ground pins of the ADC. Separate wide conductor stripe ground returns should be provided for high resolution converters to minimize noise and IR losses from the current flow in the path from the converter to the system ground point. In this way ADC supply currents and other digital logic-gate return currents are not summed into the same return path as analog signals where they would cause measurement errors.

Each of the ADC supply terminals should be capacitively decoupled as close to the ADC as possible. A large value capacitor such as 1 μF in parallel with a 0.1 μF capacitor is usually sufficient. Analog supplies are to be bypassed to the Analog Power Return pin and the logic supply is bypassed to the Logic Power Return pin.

The metal cover is internally grounded with respect to the power supplies, grounds and electrical signals. Do not externally ground the cover.

CLOCK RATE CONTROL

The AD1376 and AD1377 may be operated at faster conversion times by connecting the Clock Rate Control (Pin 23) to an external multiturn trim potentiometer (TCR <100 ppm/°C) as shown in Figure 13.

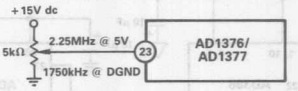

Figure 13. Clock Rate Control Circuit. AD1376 Clock Frequencies are 1.4 MHz (+5 V) and 1040 kHz (DGND).

HIGH RESOLUTION DATA ACQUISITION SYSTEM

The essential details of a high resolution data acquisition system using the AD386 and AD1376 or AD1377 are shown in Figure 14. Conversion is initiated by the falling edge of the CONVERT START pulse. This edge drives the AD1376's or AD1377's STATUS line high. The inverter then drives the AD386 into hold mode. STATUS remains high throughout the conversion and returns low once the conversion is completed. This allows the AD386 to reenter track mode.

This circuit can exhibit nonlinearities arising from transients produced at the A/D's input by the falling edge of CONVERT-START. This edge resets the A/D's internal DAC; the resulting transient depends on the SHA's present output voltage and the A/D's prior conversion result. In the circuit of Figure 14 the falling edge of CONVERT-START also places the SHA into hold mode (via the A/D's STATUS output), causing the reset transient to occur at the same moment as the SHA's track-and-hold transition. Timing skews and capacitive coupling can cause some of the transient signal to add to the signal being acquired by the SHA, introducing nonlinearity.

A much safer approach is to add a flip flop as shown in Figure 15. The rising edge of CONVERT START places the T/H into hold mode before the A/D reset transients begin. The falling edge of STATUS places the AD386 back into track mode. System throughput will be reduced if a long CONVERT START pulse is used. Throughput can be calculated from

$$Throughput = \frac{1}{T_{ACQ} + T_{CONV} + T_{CS}}$$

where T_{ACQ} is the T/H acquisition time, T_{CONV} is the time required for the A/D conversion, and T_{CS} is the duration of CONVERT START. The combination of the AD1376 and AD386

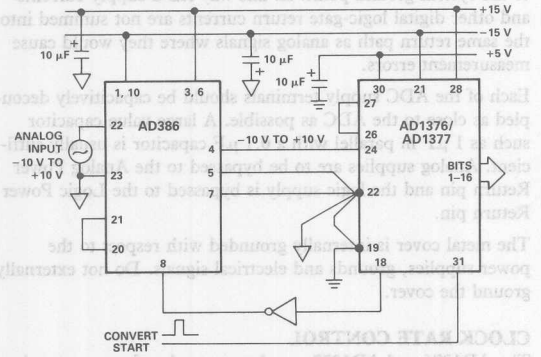

Figure 14. Basic Data Acquisition System Interconnections

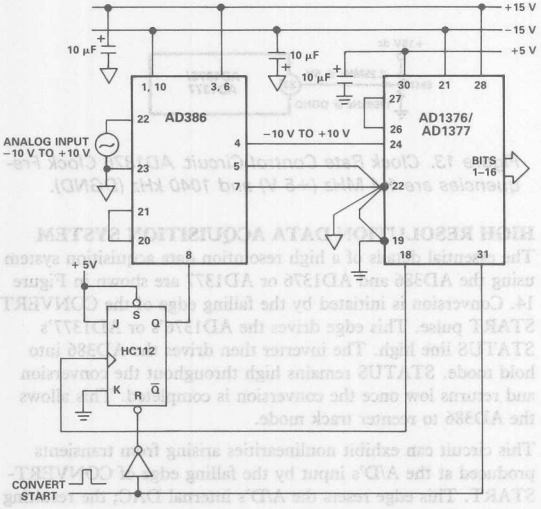

Figure 15. Improved Data Acquisition System

will provide greater than 50 kHz throughput. No significant T/H droop error will be introduced provided the width of CONVERT START is small compared with the A/D's conversion time.

Using the AD1376 or AD1377 at Slower Conversion Times

The user may wish to run the ADC at slower conversion times in order to synchronize the A/D with an external clock. This is accomplished by running a slower clock than the internal clock into the START CONVERT input. This clock must consist of narrow negative-going clock pulses, as seen in Figure 16. The pulse must be a minimum of 100 ns wide but not greater than 700 ns. Having a rising edge immediately after a falling edge inhibits the internal clock pulse. This enables the ADC to function normally and complete a conversion after 17 clock pulses. The STATUS command will function normally and switch high after the first clock pulse and will fall low after the 17th clock pulse. In this way an external clock can be used to control the ADC at slower conversion times.

Specified Over Military Temperature Range

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD1378 is a high resolution 16-bit hybrid IC analog-to-digital converter including reference, clock and laser-trimmed thin-film components. It is packaged in a compact 32-pin, ceramic DIP. The thin-film scaling resistors allow analog input ranges of ±2.5 V, ±5 V, ±10 V, 0 to +5 V, 0 to +10 V, and 0 to +20 V.

Important performance characteristics of the devices are maximum linearity error of ±0.003% of FSR, and maximum 14-bit conversion time of 15 μs. This performance is due to innovative design and the use of proprietary monolithic D/A converter chips. Laser-trimmed thin-film resistors provide the linearity and wide temperature range for no missing codes.

The AD1378 provides data in parallel and serial form with corresponding clock and status outputs. All digital inputs and outputs are TTL compatible.

APPLICATIONS

The AD1378 is excellent for use in applications requiring 14-bit accuracy over extended temperature ranges. Typical applications include multichannel data acquisition systems, servo control systems and anywhere that excellent stability and wide dynamic range in the smallest space is required. The device may be short cycled to achieve 14-bit conversions in 15 μs.

PRODUCT HIGHLIGHTS

1. The AD1378 provides 16-bit resolution with maximum linearity error less than ±0.003% (±0.006% for S grade) at +25°C.
2. Conversion time is 14 μs typical to 14 bits with short cycle capability, and 16 μs to 16 bits.
3. Two binary codes are available on the AD1378 output. They are complementary straight binary (CSB) for unipolar input voltage ranges and complementary offset binary (COB) for bipolar input ranges. Complementary twos complement (CTC) coding may be obtained by inverting Pin 1 (MSB).
4. The proprietary ICs used in this hybrid design provide excellent stability over temperature and lower chip count for improved reliability.
5. The AD1378 includes an internal reference and clock, with external clock adjust pin, and a serial output.

2

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

THEORY OF OPERATION

A 16-bit conversion A/D converter partitions the range of analog inputs into 2^{16} discrete ranges or quanta. All analog values within a given quantum are represented by the same digital code, usually assigned to the nominal midrange value. There is an inherent quantization uncertainty of ±1/2 LSB, associated with the resolution, in addition to the actual conversion errors.

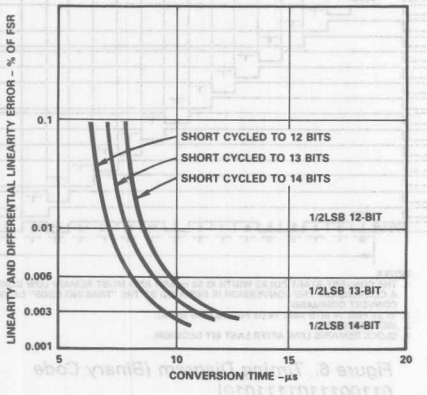

Figure 1. AD1378 Nonlinearity vs. Conversion Time

The actual conversion errors that are associated with A/D converters are combinations of analog errors due to the linear circuitry, matching and tracking properties of the ladder and scaling networks, reference error and power supply rejection. The matching and tracking errors in the converter have been minimized by the use of monolithic DACs that include the scaling network. The initial gain and offset errors are specified at ±0.2% FSR for gain and ±0.1% FSR for offset. These errors may be trimmed to zero by the use of external trim circuits as shown in Figures 3 and 4. Linearity error is defined for unipolar ranges as the deviation from a true straight line transfer characteristic from a zero voltage analog input, which calls for a zero digital output, to a point which is defined as a full scale. The linearity error is based on the DAC resistor ratios. It is unadjustable and is the most meaningful indication of A/D converter accuracy. Differential nonlinearity is a measure of the deviation in the staircase step width between codes from the ideal least significant bit step size (Figure 2).

Monotonic behavior requires that the differential linearity error be less than 1 LSB, however a monotonic converter can have missing codes; the AD1378 is specified as having no missing codes over temperature ranges as specified on the data page.

There are three types of drift error over temperature: offset, gain and linearity. Offset drift causes a shift of the transfer characteristic left or right on the diagram over the operating temperature range. Gain drift causes a rotation of the transfer characteristic about the zero for unipolar ranges or minus full scale point for bipolar ranges. The worst case accuracy drift is the summation of all three drift errors over temperature. Statistically, however, the drift error behaves as the root-sum-squared (RSS) and can be shown as:

$$RSS = \sqrt{\epsilon_G^2 + \epsilon_O^2 + \epsilon_L^2}$$

ϵ_G = Gain Drift Error (ppm/°C)
ϵ_O = Offset Drift Error (ppm of FSR/°C)
ϵ_L = Linearity Error (ppm of FSR/°C)

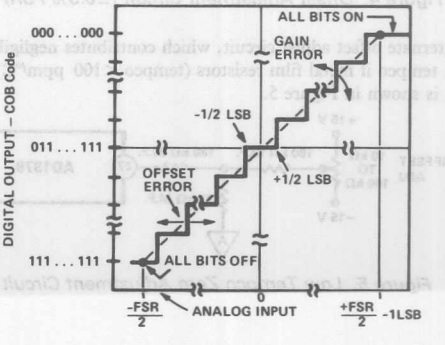

Figure 2. Transfer Characteristics for an Ideal Bipolar A/D

binary number. This conversion is accomplished as follows: the 16-bit successive-approximation register (SAR) has its 16-bit outputs connected both to the device bit output pins and to the corresponding bit inputs of the feedback DAC. The analog input is successively compared to the feedback DAC output, one bit at a time (MSB first, LSB last). The decision to keep or reject each bit is then made at the completion of each bit comparison period, depending on the state of the comparator at that time.

GAIN ADJUSTMENT

The gain adjust circuit consists of a 100-ppm/°C potentiometer connected across $\pm V_S$ with its slider connected through a 300-kΩ resistor to the gain adjust Pin 29 as shown in Figure 3.

If no external trim adjustment is desired, Pin 27 (offset adj) and Pin 29 (gain adj) may be left open.

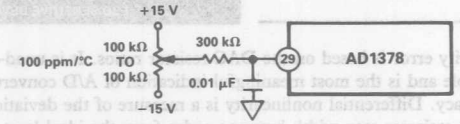

Figure 3. Gain Adjustment Circuit (±0.15% FSR)

OFFSET ADJUSTMENT

The zero adjust circuit consists of a 100-ppm/°C potentiometer connected across $\pm V_S$ with its slider connected through a 1.8-MΩ resistor to Comparator Input Pin 27 for all ranges. As shown in Figure 4, the tolerance of this fixed resistor is not critical, and a carbon composition type is generally adequate. Using a carbon composition resistor having a −1200-ppm/°C tempco contributes a worst-case offset tempco of 32 LSB_{14} × 61 ppm/LSB_{14} × 1200 ppm/°C = 2.3 ppm/°C of FSR, if the OFFSET ADJ potentiometer is set at either end of its adjustment range. Since the maximum offset adjustment required is typically no more than ±16 LSB_{14}, use of a carbon composition offset summing resistor typically contributes no more than 1 ppm/°C of FSR offset tempco.

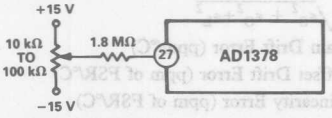

Figure 4. Offset Adjustment Circuit (±0.3% FSR)

An alternate offset adjust circuit, which contributes negligible offset tempco if metal film resistors (tempco <100 ppm/°C) are used, is shown in Figure 5.

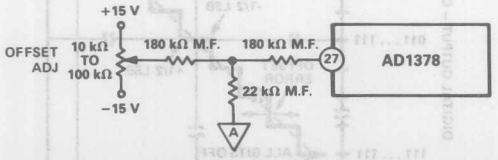

Figure 5. Low Tempco Zero Adjustment Circuit

nal noise pick-up and should be guarded by analog common.

TIMING

The timing diagram is shown in Figure 6. Receipt of a CONVERT START signal sets the STATUS flag, indicating conversion in progress. This, in turn, removes the inhibit applied to the gated clock, permitting it to run through 17 cycles. All the SAR parallel bits, STATUS flip-flops, and the gated clock inhibit signal are initialized on the trailing edge of the CONVERT START signal. At time t_0, B_1 is reset and $B_2 - B_{16}$ are set unconditionally. At t_1 the Bit 1 decision is made (keep) and Bit 2 is reset unconditionally. This sequence continues until the Bit 16 (LSB) decision (keep) is made at t_{16}. The STATUS flag is reset, indicating that the conversion is complete and that the parallel output data is valid. Resetting the STATUS flag restores the gated clock inhibit signal, forcing the clock output to the low Logic "0" state. Note that the clock remains low until the next conversion.

Corresponding parallel data bits become valid on the same positive-going clock edge.

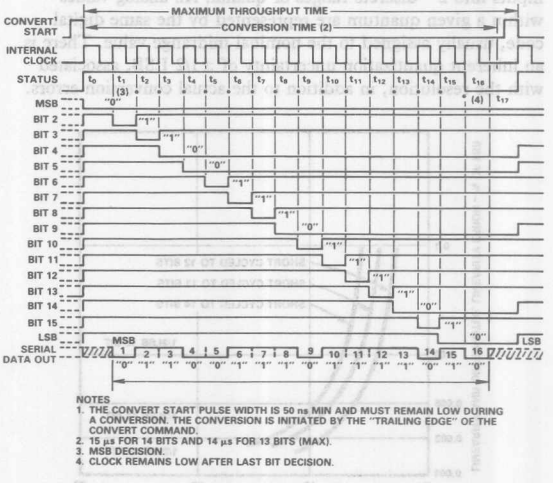

Figure 6. Timing Diagram (Binary Code 0110011101111010)

DIGITAL OUTPUT DATA

Both parallel and serial data from TTL storage registers is in negative true form (Logic "1" = 0 V and Logic "0" = 2.4 V). Parallel data output coding is complementary binary for unipolar ranges and complementary offset binary for bipolar ranges. Parallel data becomes valid at least 20 ns before the STATUS flag returns to Logic "0", permitting parallel data transfer to be clocked on the "1" to "0" transition of the STATUS flag (see Figure 7).

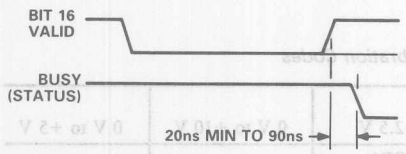

Figure 7. LSB Valid to Status Low

Serial data coding is complementary binary for unipolar input ranges and complementary offset binary for bipolar input ranges. Serial output is by bit (MSB first, LSB last) in NRZ (non-return-to-zero) format. Serial and parallel data outputs change state on positive-going clock edges. Serial data is guaranteed valid 120 ns after the rising clock edges, permitting serial data to be clocked directly into a receiving register on the negative-going clock edges as shown in Figure 8. There are 17 negative-going clock edges in the complete 16-bit conversion cycle. The first negative edge shifts an invalid bit into the register, which is shifted out on the last negative-going clock edge. All serial data bits will have been correctly transferred and be in the receiving shift register locations shown at the completion of the conversion period.

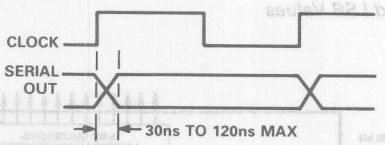

Figure 8. Clock High to Serial Out Valid

Short Cycle Input: A Short Cycle Input, Pin 32, permits the timing cycle shown in Figure 11 to be terminated after any number of desired bits has been converted, permitting somewhat shorter conversion times in applications not requiring full 16-bit resolution. When 10-bit resolution is desired, Pin 32 is connected to Bit 11 output Pin 11. The conversion cycle then terminates and the STATUS flag resets after the Bit 10 decision (timing diagram of Figure 5). Short cycle connections and associated 8-, 10-, 12-, 13-, 14- and 15-bit conversion times are summarized in Table I, for a 933 kHz clock.

Resolution Bit	Resolution (%FSR)	Maximum Conversion Time (μs)	Status Flag Reset	Connect Short Cycle Pin 32 to Pin:
16	0.0015	17.1	t_{16}	N/C (Open)
15	0.003	16.1	t_{15}	16
14	0.006	15.0	t_{14}	15
13	0.012	13.9	t_{13}	14
12	0.024	12.9	t_{12}	13
10	0.100	10.7	t_{10}	11
8	0.390	8.6	t_8	9

Table I. Short Cycle Connections

INPUT SCALING

The AD1378 inputs should be scaled as close to the maximum input signal range as possible in order to utilize the maximum signal resolution of the A/D converter. Connect the input signal as shown in Table II. See Figure 9 for circuit details.

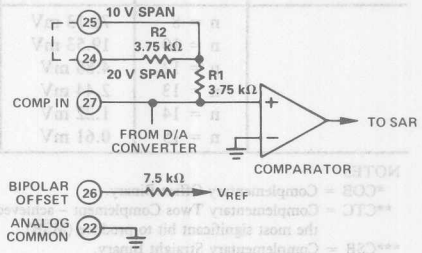

Figure 9. AD1378 Input Scaling Circuit

Input Signal Line	Output Code	Connect Pin 26 to Pin	Connect Pin 24 to	Connect Input Signal to

Table IV. Input Voltage Range and LSB Values

CALIBRATION (14-Bit Resolution Examples)
External ZERO ADJ and GAIN ADJ potentiometers, connected as shown in Figures 3 and 4, are used for device calibration. To prevent interaction of these two adjustments, Zero is always adjusted first and then Gain. Zero is adjusted with the analog input near the most negative end of the analog range (0 for unipolar and −FS for bipolar input ranges). Gain is adjusted with the analog input near the most positive end of the analog range.

0 to +10 V Range: Set analog input to +1 LSB_{14} = 0.00061 V. Adjust Zero for digital output = 11111111111110. Zero is now calibrated. Set analog input to +FSR − 2 LSB = + 9.99878 V. Adjust Gain for 00000000000001 digital output code; full-scale (Gain) is now calibrated. Half-scale calibration check: set analog input to +5.00000 V; digital output code should be 01111111111111.

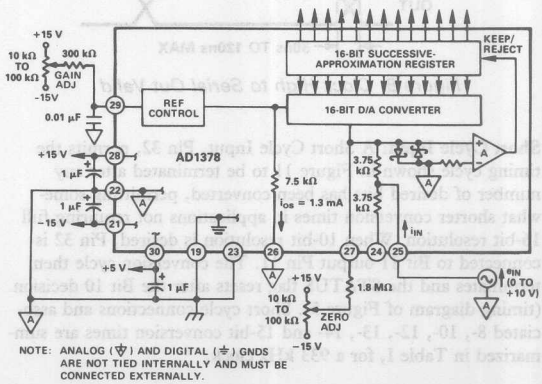

Figure 10. Analog and Power Connections for Unipolar 0 to +10 V Input Range

−10 V to + 10 V Range: Set analog input to −9.99878 V; adjust zero for 1111111111110 digital output (complementary offset binary) code. Set analog input to 9.99756 V; adjust Gain for 00000000000001 digital output (complementary offset binary) code. Half-scale calibration check: set analog input to 0.00000 V; digital output (complementary offset binary) code should be 0111111111111.

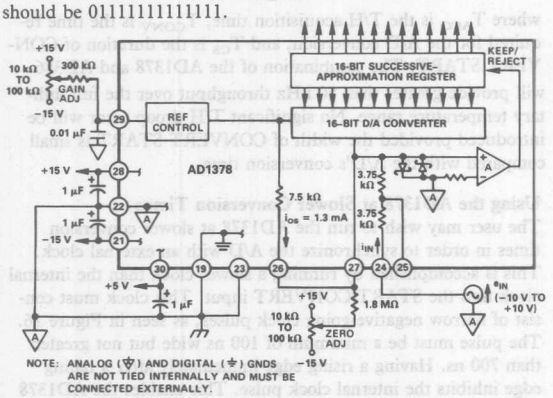

Figure 11. Analog and Power Connections for Bipolar −10 V to +10 V Input Range

Other Ranges: Representative digital coding for 0 to +10-V and −10-V to +10-V ranges is given above. Coding relationships and calibration points for 0 to +5-V, −2.5-V to +2.5-V and −5-V to +5-V ranges can be found by halving proportionally the corresponding code equivalents listed for the 0 to +10-V and −10-V to +10-V ranges, respectively, as indicated in Table III.

Zero and full-scale calibration can be accomplished to a precision of approximately ±1/2 LSB using the static adjustment procedure described above. By summing a small sine or triangular wave voltage with the signal applied to the analog input, the output can be cycled through each of the calibration codes of interest to more accurately determine the center (or end points) of each discrete quantization level. A detailed description of this dynamic calibration technique is presented in *Analog-Digital Conversion Handbook*, edited by D. H. Sheingold, Prentice-Hall, Inc., 1986.

GROUNDING, DECOUPLING AND LAYOUT CONSIDERATIONS

Many data-acquisition components have two or more ground pins which are not connected together within the device. These "grounds" are usually referred to as the Logic Power Return, Analog Common (Analog Power Return) and Analog Signal Ground. These grounds (Pins 19 and 22) must be tied together at one point for the AD1378 as close as possible to the converter. Ideally, a single solid analog ground plane under the converter would be desirable. Current flows through the wires and etch stripes of the circuit cards, and since these paths have resistance and inductance, hundreds of millivolts can be generated between the system analog ground point and the ground pins of the AD1378. Separate wide conductor stripe ground returns should be provided for high resolution converters to minimize noise and IR losses from the current flow in the path from the converter to the system ground point. In this way AD1378 supply currents and other digital logic-gate return currents are not summed into the same return path as analog signals where they would cause measurement errors.

Each of the AD1378 supply terminals should be capacitively decoupled as close to the AD1378 as possible. A large value capacitor such as 1 µF in parallel with a 0.1 µF capacitor is usually sufficient. Analog supplies are to be bypassed to the Analog Power Return pin and the logic supply is bypassed to the Logic Power Return pin.

The metal cover is internally grounded with respect to the power supplies, grounds and electrical signals. Do not externally ground the cover.

CLOCK RATE CONTROL

The AD1378 may be operated at faster conversion times by connecting the Clock Rate Control (Pin 23) to an external multiturn trim potentiometer (TCR <100 ppm/°C) as shown in Figures 12 and 13. The integral linearity and differential linearity errors will vary with speed as shown in Figure 1.

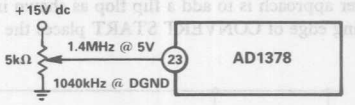

Figure 12. Clock Rate Control Circuit

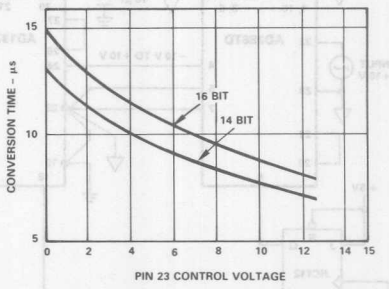

Figure 13. Conversion Time vs. Control Voltage

HIGH RESOLUTION DATA ACQUISITION SYSTEM

The essential details of a high resolution data acquisition system using the AD386 and AD1378 are shown in Figure 14. Conversion is initiated by the falling edge of the CONVERT START pulse. This edge drives the AD1378's STATUS line high. The inverter then drives the AD386 into hold mode. STATUS remains high throughout the conversion and returns low once the conversion is completed. This allows the AD386 to reenter track mode.

This circuit can exhibit nonlinearities arising from transients produced at the A/D's input by the falling edge of CONVERT-START. This edge resets the A/D's internal DAC; the resulting transient depends on the SHA's present output voltage and the A/D's prior conversion result. In the circuit of Figure 14 the falling edge of CONVERT-START also places the SHA into hold mode (via the A/D's STATUS output), causing the reset transient to occur at the same moment as the SHA's track-and-

hold transition. Timing skews and capacitive coupling can cause some of the transient signal to add to the signal being acquired by the SHA, introducing nonlinearity.

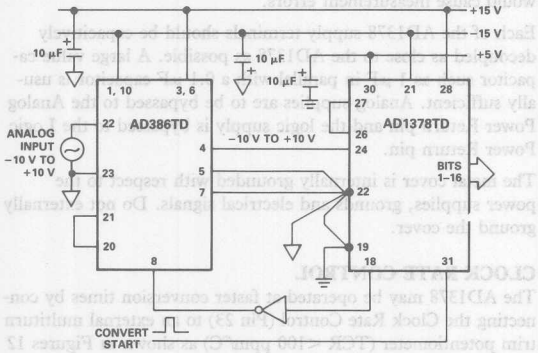

Figure 14. Basic Data Acquisition System Interconnections

A much safer approach is to add a flip flop as shown in Figure 15. The rising edge of CONVERT START places the T/H into hold mode before the A/D reset transients begin. The falling edge of STATUS places the AD386 back into track mode. System throughput will be reduced if a long CONVERT START pulse is used. Throughput can be calculated from

$$Throughput = \frac{1}{T_{ACQ} + T_{CONV} + T_{CS}}$$

where T_{ACQ} is the T/H acquisition time, T_{CONV} is the time required for the A/D conversion, and T_{CS} is the duration of CONVERT START. The combination of the AD1378 and AD386 will provide greater than 50 kHz throughput over the full military temperature range. No significant T/H droop error will be introduced provided the width of CONVERT START is small compared with the A/D's conversion time.

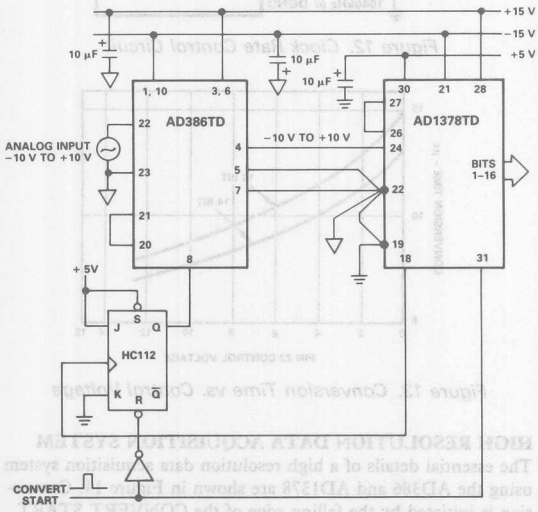

Figure 15. Improved Data Acquisition System

Using the AD1378 at Slower Conversion Times

The user may wish to run the AD1378 at slower conversion times in order to synchronize the A/D with an external clock. This is accomplished by running a slower clock than the internal clock into the START CONVERT input. This clock must consist of narrow negative-going clock pulses, as seen in Figure 16. The pulse must be a minimum of 100 ns wide but not greater than 700 ns. Having a rising edge immediately after a falling edge inhibits the internal clock pulse. This enables the AD1378 to function normally and complete a conversion after 17 clock pulses. The STATUS command will function normally and switch high after the first clock pulse and will fall low after the 17th clock pulse. In this way an external clock can be used to control the AD1378 at slower conversion times.

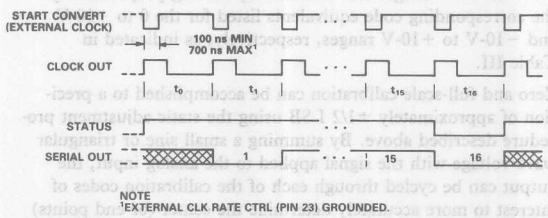

Figure 16. Timing Diagram for Use with an External Clock

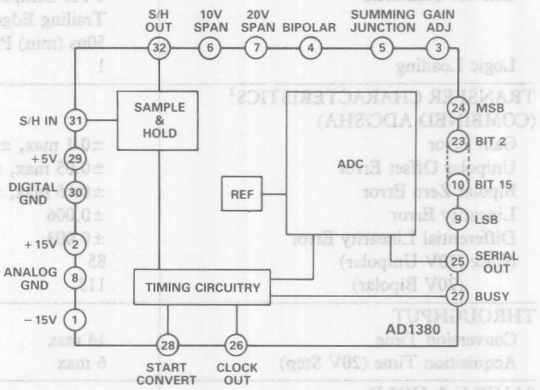
Low Cost 16-Bit Sampling ADC

AD1380



FEATURES

- Complete Sampling 16-Bit ADC With Reference and Clock
- 50kHz Throughput
- ±1/2LSB Nonlinearity
- Low Noise SHA: 300μV p-p
- 32-Pin Hermetic DIP
- Parallel and Serial Outputs
- Low Power: 900mW

APPLICATIONS

- Medical and Analytical Instrumentation
- Signal Processing
- Data Acquisition Systems
- Professional Audio
- Automatic Test Equipment (ATE)
- Telecommunications

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD1380 is a complete, low cost 16-bit analog-to-digital converter, including internal reference, clock and sample/hold amplifier. Internal thin-film-on-silicon scaling resistors allow analog input ranges of ±2.5V, ±5V, ±10V, 0 to +5V and 0 to +10V.

Important performance characteristics of the AD1380 include maximum linearity error of ±0.003% of FSR (AD1380KD) and maximum 16-bit conversion time of 14μs. Transfer characteristics of the AD1380 (gain, offset and linearity) are specified for the combined ADC/SHA, so total performance is guaranteed as a system. The AD1380 provides data in parallel and serial form with corresponding clock and status outputs. All digital inputs and outputs are TTL or 5V CMOS compatible.

ORDERING GUIDE

Model	Max Linearity Error	Temperature Range	Package Option*

THEORY OF OPERATION

A 16-bit A/D converter partitions the range of analog inputs into 2^{16} discrete ranges or quanta. All analog values within a given quantum are represented by the same digital code, usually assigned to the nominal midrange value. There is an inherent quantization uncertainty of ±1/2LSB, associated with the resolution, in addition to the actual conversion errors.

The actual conversion errors that are associated with A/D converters are combinations of analog errors due to the linear circuitry, matching and tracking properties of the ladder and scaling networks, reference error and power supply rejection. The matching and tracking errors in the converter have been minimized by the use of monolithic DACs that include the scaling network. The initial gain and offset errors are specified at ±0.1% FSR for gain and ±0.05% FSR for offset. These errors may be trimmed to zero by the use of external trim circuits as shown in Figures 2 and 3. Linearity error is defined for unipolar ranges as the deviation from a true straight line transfer characteristic from a zero voltage analog input, which calls for a zero digital output, to a point which is defined as a full scale. The linearity error is based on the DAC resistor ratios. It is unadjustable and is the most meaningful indication of A/D converter accuracy. Differential nonlinearity is a measure of the deviation in the staircase step width between codes from the ideal least significant bit step size (Figure 1).

Monotonic behavior requires that the differential linearity error be less than 1LSB, however a monotonic converter can have missing codes; the AD1380 is specified as having no missing codes over temperature ranges as specified on the data page.

There are three types of drift error over temperature: offset, gain and linearity. Offset drift causes a shift of the transfer characteristic left or right on the diagram over the operating temperature range. Gain drift causes a rotation of the transfer characteristic about the zero for unipolar ranges or minus full scale point for bipolar ranges. The worst case accuracy drift is the summation of all three drift errors over temperature. Statistically, however, the drift error behaves as the root-sum-squared (RSS) and can be shown as:

$$RSS = \sqrt{\epsilon_G^2 + \epsilon_O^2 + \epsilon_L^2}$$

ϵ_G = Gain Drift Error (ppm/°C)

ϵ_O = Offset Drift Error (ppm of FSR/°C)

ϵ_L = Linearity Error (ppm of FSR/°C)

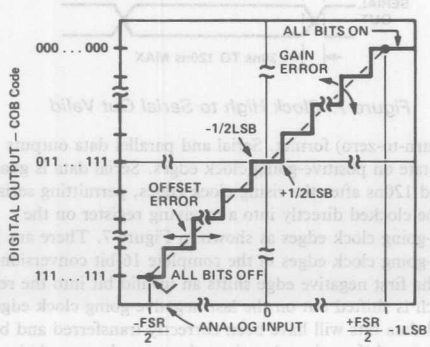

Figure 1. Transfer Characteristics for an Ideal Bipolar A/D

DESCRIPTION OF OPERATION

On receipt of a CONVERT START command, the AD1380 converts the voltage at its analog input into an equivalent 16-bit binary number. This conversion is accomplished as follows: the 16-bit successive approximation register (SAR) has its 16-bit outputs connected both to the device bit output pins and to the corresponding bit inputs of the feedback DAC. The analog input is successively compared to the feedback DAC output, one bit at a time (MSB first, LSB last). The decision to keep or reject each bit is then made at the completion of each bit comparison period, depending on the state of the comparator at that time.

GAIN ADJUSTMENT

The gain adjust circuit consists of a 100ppm/°C potentiometer connected across $\pm V_S$ with its slider connected through a 300kΩ resistor to the gain adjust Pin 3 as shown in Figure 2.

If no external trim adjustment is desired, Pin 5 (OFFSET ADJ) and Pin 3 (GAIN ADJ) may be left open.

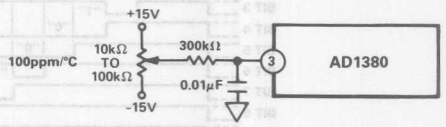

Figure 2. Gain Adjustment Circuit (±0.2% FSR)

OFFSET ADJUSTMENT

The zero adjust circuit consists of a 100ppm/°C potentiometer connected across $\pm V_S$ with its slider connected through a 1.8MΩ resistor to Comparator Input Pin 5 for all ranges. As shown in Figure 3, the tolerance of this fixed resistor is not critical, and a carbon composition type is generally adequate. Using a carbon composition resistor having a −1200ppm/°C tempco contributes a worst-case offset tempco of $32LSB_{14} \times 61ppm/LSB_{14} \times 1200ppm/°C = 2.3ppm/°C$ of FSR, if the OFFSET ADJ potentiometer is set at either end of its adjustment range. Since the maximum offset adjustment required is typically no more than $\pm 16LSB_{14}$, use of a carbon composition offset summing resistor typically contributes no more than 1ppm/°C of FSR offset tempco.

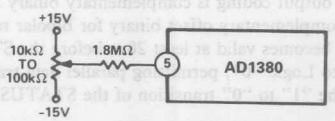

Figure 3. Offset Adjustment Circuit (±0.3% FSR)

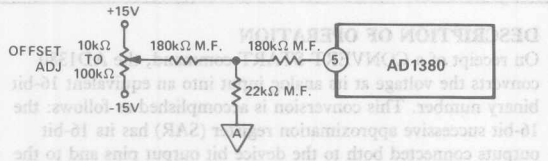
An alternate offset adjust circuit, which contributes negligible offset tempco if metal film resistors (tempco <100ppm/°C) are used, is shown in Figure 4.

In either adjust circuit, the fixed resistor connected to Pin 5 should be located close to this pin to keep the pin connection runs short. Comparator Input Pin 5 is quite sensitive to external noise pickup and should be guarded by analog common.



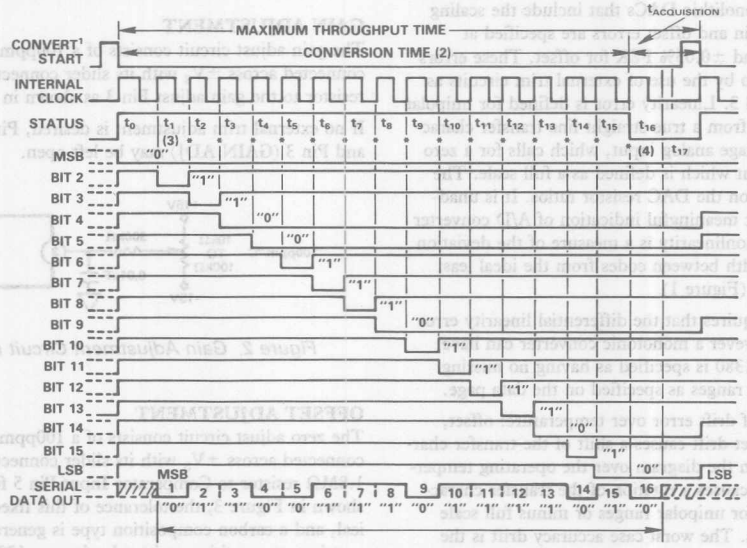


Figure 4. Low Tempco Zero Adjustment Circuit

TIMING

The timing diagram is shown in Figure 5. Receipt of a CONVERT START signal sets the STATUS flag, indicating conversion in progress. This, in turn, removes the inhibit applied to the gated clock permitting it to run through 17 cycles. All the SAR parallel bits, STATUS flip-flops and the gated clock inhibit signal are initialized on the trailing edge of the CONVERT START signal. At time t_0, B_1 is reset and $B_2 - B_{16}$ are set unconditionally. At t_1 the Bit 1 decision is made (keep) and Bit 2 is reset unconditionally. This sequence continues until the Bit 16 (LSB) decision (keep) is made at t_{16}. The STATUS flag is reset, indicating that the conversion is complete and that the parallel output data is valid. Resetting the STATUS flag restores the gated clock inhibit signal, forcing the clock output to the low Logic "0" state. Note that the clock remains low until the next conversion.

Corresponding parallel data bits become valid on the same positive-going clock edge.

NOTES
1. THE CONVERT START PULSE WIDTH IS 50ns MIN AND MUST REMAIN LOW DURING A CONVERSION. THE CONVERSION IS INITIATED BY THE "TRAILING EDGE" OF THE CONVERT COMMAND.
2. t_{CONV} = 14µs (MAX), t_{ACQ} = 6µs (MAX).
3. MSB DECISION.
4. CLOCK REMAINS LOW AFTER LAST BIT DECISION.

Figure 5. Timing Diagram (Binary Code 0110011101111010)

DIGITAL OUTPUT DATA

Both parallel and serial data from TTL storage registers is in negative true form (Logic "1" = 0V and Logic "0" = 2.4V). Parallel data output coding is complementary binary for unipolar ranges and complementary offset binary for bipolar ranges. Parallel data becomes valid at least 20ns before the STATUS flag returns to Logic "0", permitting parallel data transfer to be clocked on the "1" to "0" transition of the STATUS flag (see Figure 6).

Serial data coding is complementary binary for unipolar input ranges and complementary offset binary for bipolar input ranges. Serial output is by bit (MSB first, LSB last) in NRZ (non-return-to-zero) format. Serial and parallel data outputs change state on positive-going clock edges. Serial data is guaranteed valid 120ns after the rising clock edges, permitting serial data to be clocked directly into a receiving register on the negative-going clock edges as shown in Figure 7. There are 17 negative-going clock edges in the complete 16-bit conversion cycle. The first negative edge shifts an invalid bit into the register, which is shifted out on the last negative-going clock edge. All serial data bits will have been correctly transferred and be in the receiving shift register locations shown at the completion of the conversion period.

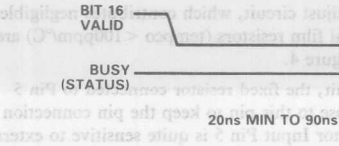

Figure 6. LSB Valid to Status Low

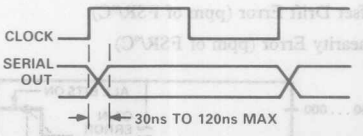

Figure 7. Clock High to Serial Out Valid

INPUT SCALING

The AD1380 inputs should be scaled as close to the maximum input signal range as possible in order to utilize the maximum signal resolution of the A/D converter. Connect the input signal as shown in Table I. See Figure 8 for circuit details.

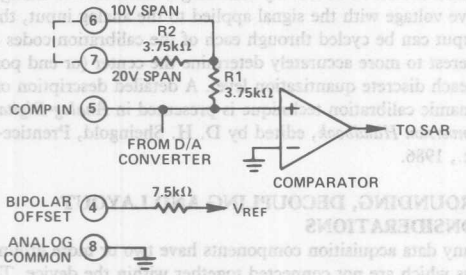

Figure 8. AD1380 Input Scaling Circuit

Input Signal Line	Output Code	Connect Pin 4 to Pin	Connect Pin 7 to	Connect Input Signal to	Connect Pin 32 to

	n = 15	0.61mV	0.31mV	0.15mV	0.31mV	0.15mV

NOTES
*COB = Complementary Offset Binary.
**CTC = Complementary Twos Complement – achieved by using an inverter to complement the most significant bit to produce ($\overline{MSB}$).
***CSB = Complementary Straight Binary.

Table III. Input Voltage Range and LSB Values

CALIBRATION (14-Bit Resolution Examples)
External ZERO ADJ and GAIN ADJ potentiometers, connected as shown in Figures 2 and 3, are used for device calibration. To prevent interaction of these two adjustments, Zero is always adjusted first and then Gain. Zero is adjusted with the analog input near the most negative end of the analog range (0 for unipolar and −FS for bipolar input ranges). Gain is adjusted with the analog input near the most positive end of the analog range.

0 to + 10V Range: Set analog input to + $1LSB_{14}$ = 0.00061V. Adjust Zero for digital output = 11111111111110. Zero is now calibrated. Set analog input to +FSR − 2LSB = + 9.99878V. Adjust Gain for 00000000000001 digital output code; full scale (Gain) is now calibrated. Half-scale calibration check: set analog input to +5.00000V; digital output code should be 01111111111111.

−10V to + 10V Range: Set analog input to −9.99878V; adjust zero for 1111111111110 digital output (complementary offset binary) code. Set analog input to 9.99756V; adjust Gain for 00000000000001 digital output (complementary offset binary) code. Half-scale calibration check: set analog input to 0.00000V; digital output (complementary offset binary) code should be 01111111111111.

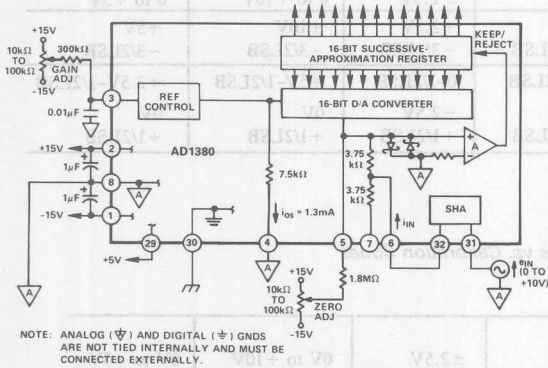

Figure 9. Analog and Power Connections for Unipolar 0 to +10V Input Range

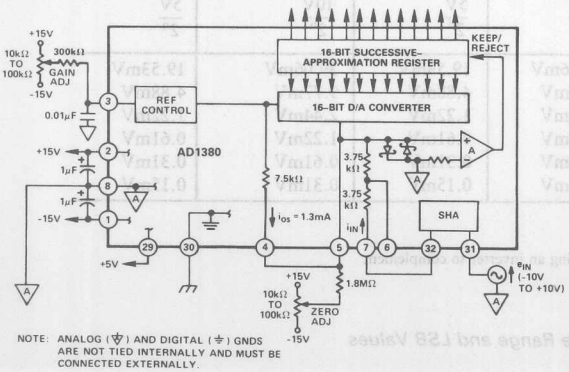

Figure 10. Analog and Power Connections for Bipolar −10V to +10V Input Range

Other Ranges: Representative digital coding for 0 to + 10V and −10V to +10V ranges is given above. Coding relationships and calibration points for 0 to +5V, −2.5V to +2.5V and −5V to +5V ranges can be found by halving proportionally the corresponding code equivalents listed for the 0 to +10V and −10V to +10V ranges, respectively, as indicated in Table II.

Zero and full-scale calibration can be accomplished to a precision of approximately ±1/2LSB using the static adjustment procedure described above. By summing a small sine or triangular wave voltage with the signal applied to the analog input, the output can be cycled through each of the calibration codes of interest to more accurately determine the center (or end points) of each discrete quantization level. A detailed description of this dynamic calibration technique is presented in *Analog-Digital Conversion Handbook*, edited by D. H. Sheingold, Prentice-Hall, Inc., 1986.

GROUNDING, DECOUPLING AND LAYOUT CONSIDERATIONS
Many data acquisition components have two or more ground pins which are not connected together within the device. These "grounds" are usually referred to as the Logic Power Return, Analog Common (Analog Power Return) and Analog Signal Ground. These grounds (Pins 8 and 30) must be tied together at one point for the AD1380 as close as possible to the converter. Ideally, a single, solid analog ground plane under the converter would be desirable. Current flows through the wires and etch stripes on the circuit cards, and since these paths have resistance and inductance, hundreds of millivolts can be generated between the system analog ground point and the ground pins of the AD1380. Separate wide conductor stripe ground returns should be provided for high resolution converters to minimize noise and IR losses from the current flow in the path from the converter to the system ground point. In this way AD1380 supply currents and other digital logic-gate return currents are not summed into the same return path as analog signals where they would cause measurement errors.

Each of the AD1380 supply terminals should be capacitively decoupled as close to the AD1380 as possible. A large value capacitor such as 1μF in parallel with a 0.1μF capacitor is usually sufficient. Analog supplies are to be bypassed to the Analog Power Return pin and the logic supply is bypassed to the Logic Power Return pin.

The metal cover is internally grounded with respect to the power supplies, grounds and electrical signals. Do not externally ground the cover.

APPLICATION

AD1380 Dynamic Performance

High performance sampling analog-to-digital converters like the AD1380 require dynamic characterization to assure they meet or exceed their desired performance parameters for signal processing applications. Key dynamic parameters include signal-to-noise ratio (SNR) and total harmonic distortion (THD), which are characterized using Fast Fourier Transform (FFT) analysis techniques.

The results of that characterization are shown in Figure 11. In the test a 13.2kHz sine wave is applied as the analog input (f_O) at a level of 10dB below full scale; the AD1380 is operated at a word rate of 50kHz (its maximum sampling frequency).

The results of a 1024-point FFT demonstrate the exceptional performance of the converter, particularly in terms of low noise and harmonic distortion.

In Figure 11, the vertical scale is based on a full scale input referenced as 0dB. In this way, all (frequency) energy cells can be calculated with respect to full scale rms inputs.

The resulting signal-to-noise ratio is 83.2dB, which corresponds to a noise floor of −93.2dB.

Total harmonic distortion is calculated by adding the RMS energy of the first four harmonics and equals −97.5dB. Increasing the input signal amplitude to −0.4dB of full scale, causes THD to increase to −80.6dB as shown in Figure 12.

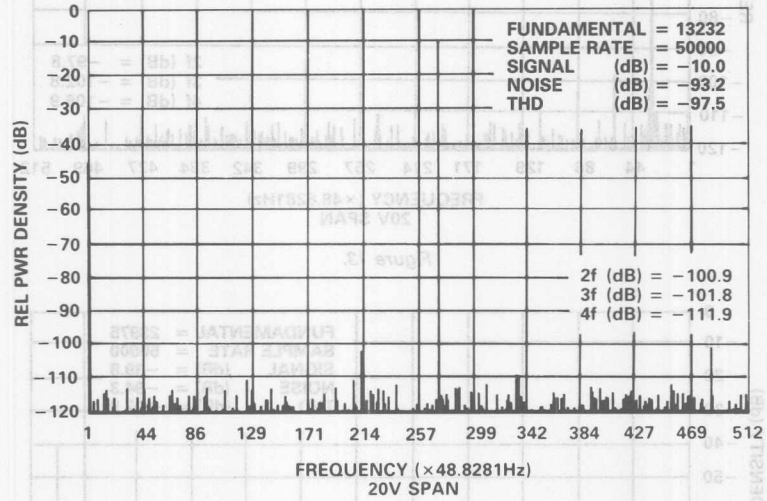

Figure 11.

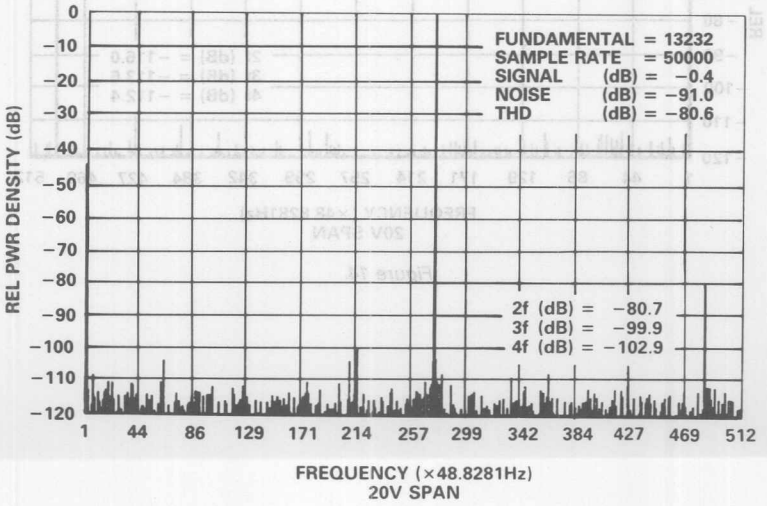

Figure 12.

At lower input frequencies, however, THD performance is improved. Figure 13 shows a full scale (−0.3dB) input signal at 1.41kHz. THD is now −96.0dB.

The ultimate noise floor can be seen with low level input signals of any frequency. In Figure 14 the noise floor is at −94dB, as demonstrated with an input signal of 24kHz at −39.8dB.

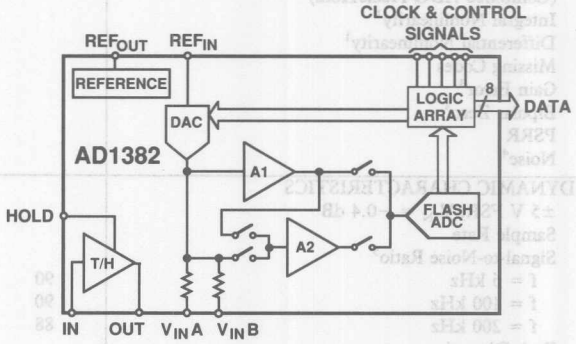
16-Bit 500 kHz Sampling ADC

AD1382



PRODUCT FEATURES

- Single Package
- 16-Bit Resolution
- 500 kHz Sampling Rate
- SNR 90 dB @ 100 kHz (min)
- THD −88 dB @ 100 kHz (min)
- 0.0015% FSR INL (typ)
- ±5, ±10 V Bipolar Input
- Zero Offset Autocalibration

APPLICATIONS

- Medical Imaging
  - CAT
  - Magnetic Resonance
- Vibration Analysis
- Parametric Measurement Unit (ATE)
- Waveform/Transient Recorders
- Analytical Instruments
- Sonar
- Radar

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD1382 is a complete 500 kHz, 16-bit, sampling analog-to-digital converter contained in a single package. This high resolution, high speed converter offers outstanding noise and distortion performance along with excellent INL and DNL performance, all in a single dual-in-line package.

The AD1382 guarantees outstanding noise and distortion performance for both ±5 V and ±10 V input ranges. The AD1382 architecture includes a low noise and low distortion track/hold with a three-pass digitally corrected subranging ADC. Precision thin film resistors and a new proprietary DAC provide for outstanding dynamic and static performance. Output data is multiplexed over an eight-bit CMOS/TTL compatible data bus.

The AD1382 uses four power supplies, ±5 V and ±15 V, and an external 10 MHz clock. Power dissipation is nominally 2.8 W. Two user selectable bipolar input ranges, ±5 V and ±10 V are provided. Careful attention to grounding and a single package make it easy to design PCBs to achieve specified performance.

AD1382—SPECIFICATIONS (T_A = +25°C, V_S = ±15 V, V_{DD} = +5 V, V_{SS} = −5 V, 10 MHz External Clock, 5 Minute Warm-up, unless otherwise noted)

NOTES

[1]Integral linearity is inferred from FFT. Differential linearity is derived from histogram.

[2]FSR, full-scale range.

[3]Adjustable to zero.

[4]Noise based on small signal FFT excluding quantization noise.

[5]SNR fundamental to noise minus harmonics 2–9.

[6]THD includes harmonics 2–9 of the fundamental.

[7]Aperture delay is the time from the rising edge on the Hold Command Input to the opening of the switch in the Track/Hold.

[8]Guaranteed but not 100% production tested.

[9]Timing based on 10 MHz clock. Refer to Figures 13 and 14.

[10]Case to ambient temperature is assumed to be 30°C. The AD1382 case temperature will stabilize about 30°C above ambient while operating in free air without a heat sink. Factory calibration is done in this condition. See the application section for further information.

Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS

$+V_S$ to AGND . . . . . 18 V
$-V_S$ to AGND . . . . . −18 V

*Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

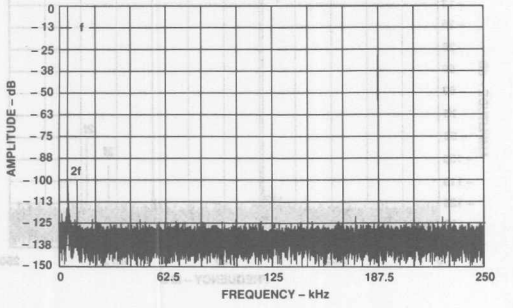
AD1382 PIN CONNECTIONS

The AD1382 is housed in a 48-pin bottom-brazed ceramic bathtub package. The pinout is as follows:

PIN	FUNCTION	PIN	FUNCTION
1	CLOCK IN	48	V_{DD2} (+5 V POWER)
2	POWER GROUND	47	POWER GROUND
3	B1/B9 MSB	46	V_{SS2} (−5 V POWER)
4	B2/B10	45	AUTOZERO
5	B3/B11	44	B1 SELECT
6	B4/B12	43	POWER GROUND
7	B5/B13	42	POWER GROUND
8	B6/B14	41	DNC
9	B7/B15	40	GAIN ADJUST
10	B8/B16 LSB	39	+10 V REFERENCE OUT
11	V_{DD1} (+5 V SIGNAL)	38	$-V_{S1}$ (−15 V)
12	POWER GROUND	37	SIGNAL GROUND
13	V_{SS1} (−5 V SIGNAL)	36	$+V_{S1}$ (+15 V)
14	SIGNAL GROUND	35	SIGNAL GROUND
15	DATA STROBE	34	DNC
16	HI/LO BYTE SELECT	33	DNC
17	OE DATA ENABLE	32	+10 V REFERENCE IN
18	START CONVERT	31	V_{IN} B
19	HOLD COMMAND OUT	30	V_{IN} A
20	SIGNAL GROUND	29	OFFSET ADJUST
21	$+V_{S2}$ (+15 V)	28	DNC
22	HOLD COMMAND IN	27	TRACK/HOLD OUTPUT
23	$-V_{S2}$ (−15 V)	26	SIGNAL GROUND
24	POWER GROUND	25	TRACK/HOLD INPUT

DNC = DO NOT CONNECT

CAUTION



ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

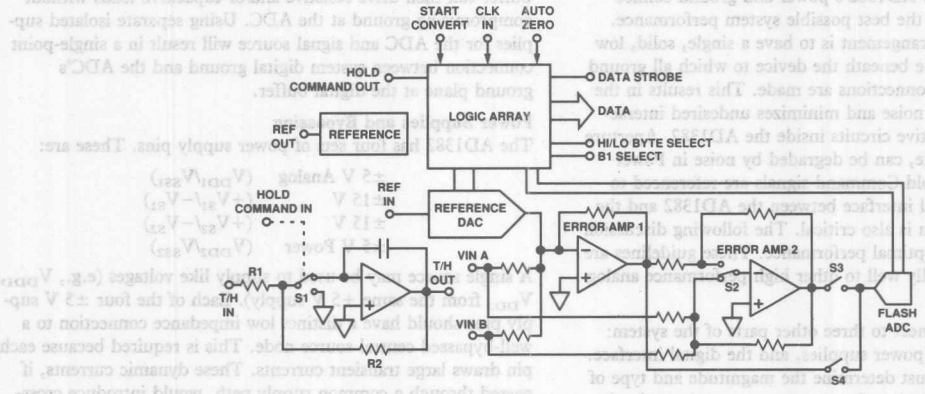

Figure 9. AD1382 Functional Block Diagram

THEORY OF OPERATION

The AD1382 performs conversions using a three-pass subranging technique. This proven circuit concept, implemented with state of the art components, allows the ADC, track-hold, and a low noise reference to fit into a single hermetic package, simplifying the task of board design. The T/H and ADC portions of the AD1382 are distinct circuits with inputs and outputs available on separate pins. This functional division allows greatest application flexibility. The AD1382's major functional blocks are shown in Figure 9.

The T/H uses a low noise high performance hybrid amplifier and high speed analog switches to achieve precision performance. It operates as an inverting amplifier during Track mode. Summing junction switch S1 disconnects the analog input to place the circuit into Hold mode; the amplifier's output stays constant because the dc path to its inverting input is broken. S1 also grounds the junction of R1 and R2 to minimize signal feedthrough. Pedestal is independent of the analog input level because all switching is done near ground. This ensures very low nonlinearity and distortion.

A precision reference DAC and an 8-bit flash ADC form the heart of the AD1382's subranging design. High speed amplifiers combine the analog input and DAC output to produce the voltages encoded by the flash ADC during each pass. A logic array provides all necessary timing, control, and computation.

The first rising clock edge after Start Convert goes high begins the conversion (provided the previous conversion is complete). The Hold Command goes high and switches the T/H into hold. The held signal from the T/H goes through S2, S3, and Error Amp 2 to the flash ADC. During this pass Error Amp 2 actually attenuates the ADC input to keep the voltage within the flash ADC's input range. The flash ADC is strobed after a 100 ns settling period. The 8-bit result is saved in the logic array and is routed to the MSBs of the reference DAC.

Error Amp 1 amplifies the difference between the reference DAC output and the held input signal during the second pass. S4 routes this error signal to the flash ADC, which is strobed a second time after Error Amp 1 has settled. The new 8-bit result is used to correct the previous result, increasing the accuracy of this intermediate answer to 13-bit precision. Following this the reference DAC is updated.

Both error amplifiers are active during the third pass. S2 is switched, allowing Error Amp 2 to amplify Error Amp 1's output. S3 now brings Error Amp 2's output to the flash ADC. The flash ADC is strobed a final time after the DAC and both error amplifiers have settled. The logic array combines the data from the third flash conversion with the earlier 13-bit word to produce the final 16-bit result. The T/H is returned to track mode, and Error Amp 2 is reconnected as an attenuator 50 ns after the completion of the third flash conversion to prepare for the next conversion.

The output data are placed on the data bus in two 8-bit bytes to be read by the host system. The Data Strobe output synchronizes the data transfer by providing a rising edge for the first byte and a falling edge for the second byte. The Hi/Lo Byte Select input allows the user to choose which data byte is presented first. B1 Select sets the polarity of the MSB to provide either twos complement or offset binary data.

CONNECTION AND OPERATION OF THE AD1382

Analog Input

The analog input should be connected to the Track/Hold Input (Pin 25). Two pin programmable operating ranges are available: ±5 V and ±10 V. Connect the Track/Hold Output to V_{IN} A and/or V_{IN} B as follows:

Desired Scale	Connect V_{IN} A to	Connect V_{IN} B to
±5 V	Track/Hold Output	Track/Hold Output
±10 V	Track/Hold Output	Analog Signal GND

Harmonic distortion is lower when using the ±5 V range, while noise is lower when using the ±10 V range.

The AD1382's noise and distortion performance exceed the capability of most signal sources. Maintaining this performance at the system level requires attention to every detail of grounding, bypassing, and signal sources. A low impedance high bandwidth signal source is essential to achieve low distortion. Few monolithic amplifiers exist which can maintain signal fidelity at levels comparable with the AD1382's performance, even at low frequencies. High bandwidth means increased noise and decreased SNR. See *Testing the AD1382* for techniques of achieving the lowest possible noise and distortion.

Grounding

Proper treatment of the AD1382's power and ground connections is vital to achieve the best possible system performance. The ideal grounding arrangement is to have a single, solid, low impedance ground plane beneath the device to which all ground and supply bypassing connections are made. This results in the lowest possible ground noise and minimizes undesired interactions between the sensitive circuits inside the AD1382. Aperture uncertainty, for example, can be degraded by noise in Power Ground because the Hold Command signals are referenced to this ground. The digital interface between the AD1382 and the rest of the user's system is also critical. The following discussion will help in obtaining optimal performance. These guidelines are general and apply equally well to other high performance analog and digital circuits.

The AD1382 must connect to three other parts of the system: the input signal(s), the power supplies, and the digital interface. The system designer must determine the magnitude and type of ground currents and whether they are constant or dynamic. A system block diagram is a valuable aid to understanding how grounds should be connected for good performance. Figure 10 shows recommended ground connections for the AD1382 in a typical system.

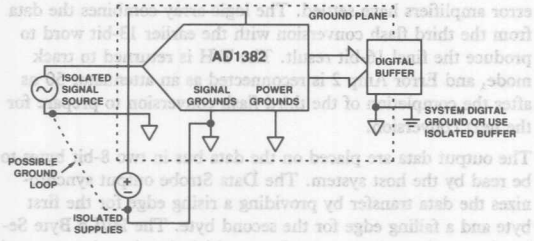

Figure 10. AD1382 Grounding

The AD1382 has a net ground current of about 40 mA. Most of this flows in the power grounds. There are also substantial dynamic currents in the power grounds. The signal grounds have primarily low level static (dc) currents. Signal and power grounds are separated inside the hybrid because the resistance and inductance inherent in thick-film construction would cause interactions between ground currents, leading to poor performance. (Remember that an LSB can be as small as 156 μV.)

Care must be taken to prevent the AD1382's ground currents from flowing in the signal ground between the signal source and the AD1382 if this ground has significant resistance. This is not usually a problem if the signal source is located on the same board as the AD1382 because the resistance can be made very low through the use of a ground plane.

The signal source's ground and supply currents must be considered when the source and ADC share common power supplies. A ground loop formed by the AD1382, the signal source, and the power supplies can cause significant errors.

The connection between the AD1382's ground plane and the system's digital ground is best made away from the AD1382. This will prevent noisy system ground currents from passing through critical parts of the ADC. In a very noisy environment it may be wise to isolate the entire analog circuit. Figure 10 shows the required isolation provided by a digital buffer. The buffer can then drive resistive and/or capacitive loads without compromising ground at the ADC. Using separate isolated supplies for the ADC and signal source will result in a single-point connection between system digital ground and the ADC's ground plane at the digital buffer.

Power Supplies and Bypassing

The AD1382 has four sets of power supply pins. These are:

±5 V Analog	(V_{DD1}/V_{SS1})
±15 V	($+V_{S1}/-V_{S1}$)
±15 V	($+V_{S2}/-V_{S2}$)
±5 V Power	(V_{DD2}/V_{SS2})

A single source may be used to supply like voltages (e.g., V_{DD1}, V_{DD2} from the same +5 V supply). Each of the four ±5 V supply pins should have a distinct low impedance connection to a well-bypassed central source node. This is required because each pin draws large transient currents. These dynamic currents, if passed through a common supply path, would introduce crosstalk and increase the AD1382's apparent noise. The two sets of ±15 V supplies need not be split in this fashion.

Every AD1382 supply pin should be bypassed to the ground plane with a high quality ceramic capacitor of 0.01 μF to 0.1 μF. This capacitor should be located as close as possible to the AD1382 to minimize lead lengths. Each V_{DD} and V_{SS} pin must also be bypassed to the ground plane with a 10 μF solid tantalum bypass capacitor located close to the AD1382. Ten microfarad bypass capacitors for $\pm V_{S2}$ (Pins 21 and 23) are also necessary. These power distribution concepts are shown in Figure 11.

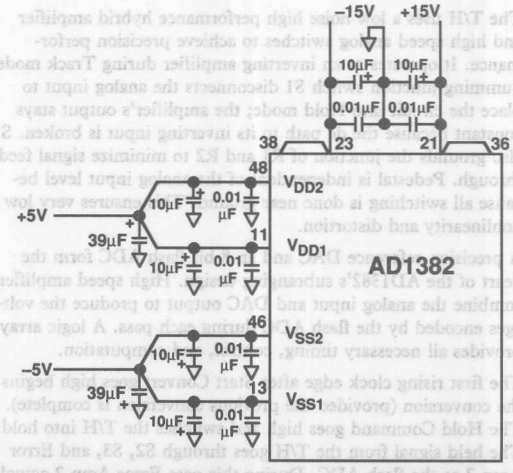

Figure 11. Recommended AD1382 Supply Distribution. All 10 μF and 0.01 μF Capacitors Must Be Located Close to the AD1382. Make All Ground Connections to Groundplane

All power supplies should be of the linear type. Switching power supplies are not recommended as they can introduce considerable high frequency noise into sensitive analog signal paths, degrading the AD1382's apparent performance.

Supply pins of equivalent voltage should not be allowed to differ by more than 0.3 V.

If separate ground planes are used for Signal and Power Ground, the supplies should be bypassed as follows:

Supply	Bypass to
±5 V Analog	Signal Ground
±15 V ($+V_{S1}/-V_{S1}$)	Signal Ground
±15 V ($+V_{S2}/-V_{S2}$)	Power Ground
±5 V Power	Power Ground

Care is also required when using a +5 V powered crystal oscillator to provide the AD1382's clock signal. These devices produce considerable supply noise and proper bypassing is essential. The oscillator should be bypassed with both ceramic and solid tantalum capacitors using minimum lead lengths. A 10 Ω resistor in series with the +5 V supply provides additional isolation and low pass filtering of transients produced by the oscillator.

Reference

The AD1382 has an excellent internal reference with a typical temperature coefficient of 5 ppm/°C. The Reference Out (Pin 39) is normally connected to Reference In (Pin 32). An external reference may be connected to the reference input if desired. The reference input pin requires negligible current. The reference input voltage should not exceed +11 V and must remain more positive than −0.3 V. The reference output requires no bypassing and should not be capacitively loaded. If an external reference is used, it must have low noise to avoid degrading the signal to noise ratio of the AD1382.

The reference output can source up to 2 mA of static (dc) current without affecting the performance of the AD1382.

DIGITAL INTERFACES

10 MHz Clock

The AD1382 requires a stable external clock. A 10 MHz clock provides a sample rate of 500 kilosamples per second. Since the ADC operates synchronously with this clock, clock phase noise will appear as jitter in the aperture time. Lower clock frequencies may be used, and the sample rate will be reduced proportionately.

Standard TTL and CMOS crystal oscillator modules may be used successfully to generate the required 10 MHz clock signal. These oscillators often create considerable power supply transient noise. The oscillator should be bypassed with both ceramic and solid tantalum capacitors using minimum lead lengths. A 10 Ω resistor in series with the +5 V supply provides additional isolation and low-pass filtering of transients produced by the oscillator. See Figure 12.

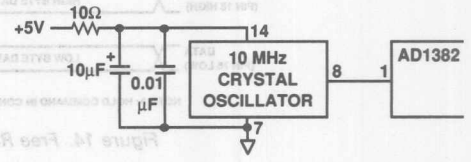

Figure 12. Isolating Clock Noise. Bypass Capacitors Should Be Located Close to the Oscillator

START CONVERT (Pin 18)

Synchronous Operation

The Start Convert signal acts like the data input of a flip-flop. A conversion begins on the first rising clock edge after Start Convert goes high (provided setup time requirements are met). This edge drives Hold Command Out high, switching the T/H into Hold mode. Hold Command Out (Pin 19) should be connected to Hold Command In (Pin 22) for synchronous operation. Continuous conversions at a 500 kHz rate may be obtained by holding Start Convert high. The 10 MHz clock may be divided down and used to drive the Start Convert input when a lower conversion rate is desired. This will provide clock-synchronized conversions at the lower rate. Synchronous conversion timing is shown in Figures 13 and 14.

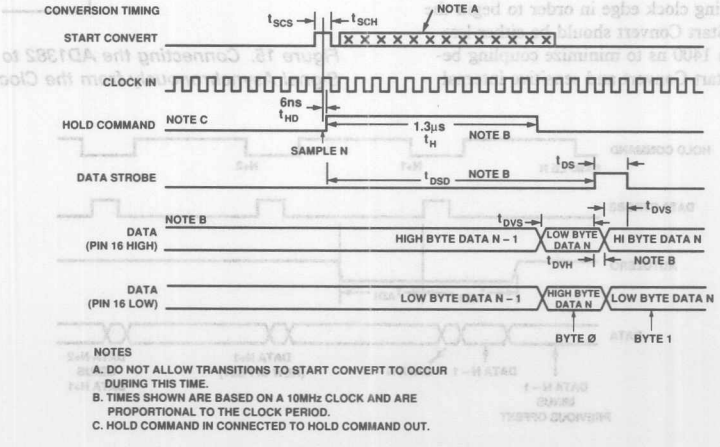

Figure 13. Start-Convert Controlled Conversion Timing

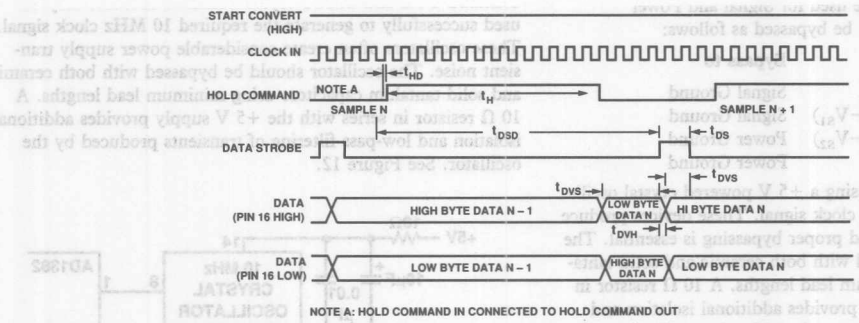

Figure 14. Free Running Conversion Timing

Start Convert may also be used as a gate to capture data only in a time window. The rising and falling edges of Start Convert define the beginning and end of the window during which conversions are desired.

Some restrictions apply to the timing of Start Convert. Transitions on the Start Convert pin should be limited to the 700 ns interval before the rising edge of Hold Command Out and to the 100 ns period after this edge. This minimizes coupling between Start Convert and sensitive internal circuit nodes.

Asynchronous Operation

In synchronous operation the T/H is placed into Hold mode by the first rising clock edge after Start Convert goes high. This mode of operation provides maximum rejection of system clock noise. Some applications may require the AD1382 to operate asynchronously, that is, with the Start Convert input directly controlling the track-to-hold transition. This may be achieved using a 2-input OR gate connected as shown in Figure 15. The rising edge of Start Convert places the T/H into Hold mode; the A/D conversion cycle begins with the first rising clock edge after the Start Convert transition, and Start Convert must remain high during at least one rising clock edge in order to begin the conversion. The width of Start Convert should be either less than 150 ns or greater than 1400 ns to minimize coupling between the falling edge of Start Convert and sensitive internal nodes. In asynchronous operation the T/H will remain in Hold mode as long either Hold Command Out or Start Convert is high. System timing requires careful scrutiny to ensure that the T/H has a minimum of 700 ns for signal acquisition before another conversion begins. The minimum width of Start Convert is 20 ns, the sum of t_{SCS} and t_{SCH}, the minimum setup and hold times.

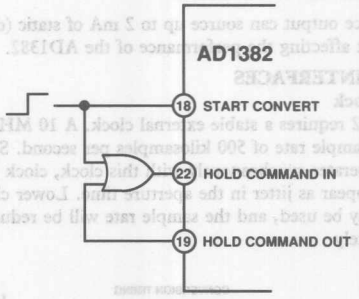

Figure 15. Connecting the AD1382 to Sample the Input Signal Asynchronously from the Clock

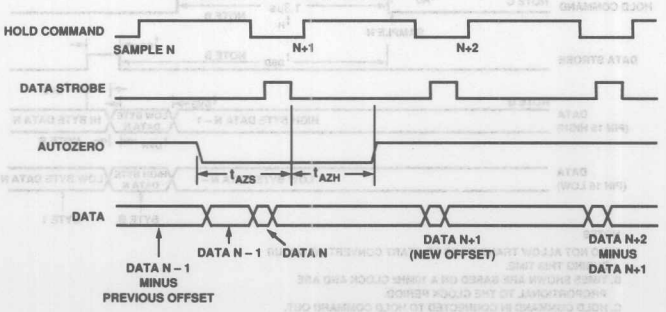

Figure 16. Autozero Cycle Operation

Output Data

The output data are multiplexed in two bytes onto an 8-bit data bus. Data are guaranteed to be stable at the time of the edges of Data Strobe (Pin 15). Hi/Lo Byte Select (Pin 16) controls which byte is presented first. If Hi/Lo Byte Select is high, then BYTE0 is B9–B16 and BYTE1 is B1–B8. The order of the data bytes is interchanged when Hi/Lo Byte Select is low. BYTE 0 and BYTE 1 are defined in the timing diagram Figure 13. B1 is the most significant bit of the reconstructed 16-bit data.

B1 SELECT (Pin 44) determines whether data is presented in complementary twos complement or complementary offset binary form. Complementary twos complement data is provided when B1 Select is LOW. $\overline{OE}$ may be used to place the data bus into a high impedance state.

The arithmetic unit in the AD1382 saturates at all 0s or all 1s if the input range is exceeded.

AUTOZERO (Pin 45)

The Autozero function may be used to digitally correct internal offsets in the Track/Hold and ADC as well as external offsets. To use Autozero the Track/Hold input must be connected to a zero reference prior to the zeroing conversion. This connection is external to the AD1382 and must be provided by the user; the resistance of this connection is not critical but should be less than 1000 Ω. An Autozero cycle forces the AD1382's digital output to indicate exactly zero when its input is at the zero point, nominally 0 V. (This assumes that the twos complement data format is used. Autozero forces the digital output to mid-scale when the selected data format is offset binary.) Autozero operates by storing the digital result of a zeroing conversion and subtracting it from all subsequent conversion results. This reduces the maximum nonsaturating input of the AD1382 a small amount at one end of its range depending on the magnitude and polarity of the offset.

The Autozero feature is enabled by driving the Autozero Input (Pin 45) low at the time of a falling edge at the Data Strobe output. Offset data will be stored on the first falling edge of Data Strobe after Autozero is brought high; the offset data are also available on the AD1382's data bus during this Data Strobe pulse. Autozero operation is illustrated in Figure 16. All subsequent A/D conversions will be digitally corrected by the offset term as long as Autozero remains high. The offset register is cleared when Autozero goes low and the contents of the data output registers will revert to their uncorrected value. Figure 17 shows Autozero timing requirements. Autozero cannot be activated until the first conversion after powerup has been completed.

The Autozero feature may be disabled by keeping Autozero low.

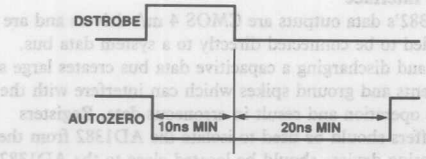

Figure 17. Autozero Setup and Hold Times

GAIN ADJUST (Pin 40)

The internal reference of the AD1382 may be adjusted by varying the voltage applied to the Gain Adjust pin. The input impedance of this pin is nominally 20 kΩ, with a tolerance of ±20%. A change of 1 V on Pin 40 will change the reference voltage by about 10 mV. The reference may be adjusted by ±150 mV without degrading the AD1382's performance. The simplest method of implementing the gain adjust is to connect a potentiometer between the ±15 V supplies, with the wiper connected to the Gain Adjust pin. Care should be taken to ensure that noise does not enter the ADC through the Gain Adjust pin.

Figure 18a. AD1382 Gain Adjust Circuit

OFFSET ADJUST (Pin 29)

The ADC's offset voltage may be adjusted by means of a voltage applied to the Offset Adjust pin. The nominal adjustment sensitivity is 0.005% FSR/V. The input impedance is 20 kΩ with a ±20% tolerance. The simplest way to implement the offset adjust is to connect a potentiometer between the ±15 V supplies, with the wiper connected to the Offset Adjust pin. Care should be taken to ensure that noise does not enter the ADC through the Offset Adjust pin.

Figure 18b. AD1382 Offset Adjust Circuit

APPLICATIONS

Mounting and Thermal Considerations

Although the AD1382 will operate over a wide temperature range, best performance is obtained by maintaining the case temperature between 40°C and 70°C. This can usually be achieved without a heat sink provided there is a moderate amount of air flow. Under these conditions the case temperature will rise about 20°C. Performance will degrade gradually outside the specified temperature range due to linearity drift in the reference DAC.

System thermal analysis or experimental evidence may show that a heat sink is necessary. A thin heat transfer plate can be mounted under the package to conduct heat into the ground plane. This plate may be made of metal or from an elastomeric heat conducting material. Elastomeric materials will conform to the board and to the AD1382 package to improve heat transfer while reducing mechanical stress. They also have the advantage of not requiring thermally conductive grease.

Testing the AD1382

It is difficult to test the AD1382 with ordinary test methods because of the part's very low distortion and noise. The number of output codes and the nature of the analog to digital conversion make static tests of performance especially cumbersome. Subranging converters with error correction circuitry can have flaws at any place in their transfer function and all codes must be exercised for a complete test.

Histograms provide a convenient way to measure all codes in a modest amount of time. Even histograms can be slow, though, when 20 million conversions (40 seconds) may be required to achieve statistically valid results.

Distortion and dynamic range tests based on FFTs are the most powerful tests. They quantify noise and nonlinearity as a function of input frequency. From them one can infer qualitative integral and differential nonlinearity performance while determining the ADC's specific dynamic performance. FFTs are especially useful for systems which require excellent dynamic response, such as magnetic resonance imaging. They also uncover performance problems that don't show up in static tests of linearity.

The difficulty in doing FFT tests stems from the requirement for ultra pure sine wave inputs at various frequencies over the operating bandwidth of the ADC. Even the best available generators are not capable of supplying signals with sufficiently low noise and low distortion for testing the AD1382. Few generators permit phase-locking to the ADC clock. Phase-locking makes it possible to obtain an integral number of cycles of the input sine wave within the FFT data window, which in turn eliminates the need for windowing functions and the spectral spreading they cause.

The best generator currently available for this purpose is the Brüel and Kjær Model 1051 (or 1049). This generator provides a programmable output frequency up to 250 kHz with better than 0.001 Hz resolution. The generator's distortion performance at frequencies below 20 kHz is better than the AD1382 but degrades at 100 kHz and higher. Noise is a problem at all frequencies, being about −85 dB over the AD1382's bandwidth. Both noise and distortion can be reduced to acceptable levels with filters. Passive filters with narrow bandwidth will reduce harmonic distortion to less than −100 dB. Inductors wound on large pot cores with air gaps can be made quite linear, and with careful winding will provide low loss and low capacitance. Such filters will reduce noise to negligible levels outside their pass band to provide a much better view of actual ADC performance. The effect of aperture jitter, for example, cannot be observed without a filter.

The FFTs shown in Figures 1–8 were produced using these methods. These tests are done as a normal part of production testing to guarantee the dynamic performance of the AD1382.

High Impedance Inputs

Using the AD1382 in multiplexed applications requires buffering the part's 2.5 kΩ input impedance to eliminate the distorting effects of nonlinear multiplexer on-resistance. The choice of buffer amplifier depends on the nature of the input signals.

"Static" Applications

Amplifier noise, CMRR linearity, and settling time are of primary importance when the inputs are low frequency or DC. This is the case in a CAT scan imager, for example, when signals are produced by integrating photocurrents. Noise limits ultimate system resolution. The AD1382 has a typical input-referred noise of 55 μV rms. Buffer noise must be added to this in a root-sum-squares fashion to determine total system noise. A buffer amplifier which adds noise of 18 μV rms, for example, will result in a system noise level of $(18^2+55^2)^{1/2} = 58$ μV rms, a negligible increase. Detailed system noise calculations require knowledge of the buffer's noise spectral density and equivalent noise bandwidth. The AD1382's equivalent noise bandwidth is 2.2 MHz. *Low Noise Electronic Design* (C.D. Motchenbacher and F.C. Fitchen, John Wiley and Sons, New York, 1973) provides excellent discussions of noise analysis and calculations.

Buffer amplifier CMRR produces an apparent gain error as long as the value of CMRR is independent of signal level. The size of this "gain error" is directly related to the actual value of CMRR; an amplifier with 60 dB CMRR will create an apparent gain error of 0.1%. The precise value of CMRR is not critical as long as it remains constant with signal level. Any variation in CMRR with input level will introduce nonlinearity. The smaller the value of CMRR (in dB), the more critical variations in this value become. An amplifier with CMRR ranging from 100 dB to 110 dB over the range of −10 V to +10 V will produce negligible nonlinearity, while an amplifier whose CMRR varies from 60 dB to 70 dB over the same range would be completely unacceptable.

Buffer settling time will affect the system's throughput. The system sample rate can be maintained at 500 kHz provided the buffer's settling time is less than about 1.7 microseconds. The input channel should be switched just after the AD1382's SHA enters Hold mode as indicated by a rising edge at Hold Command In (Pin 22).

"Dynamic" Applications

Dynamic applications complicate the choice of buffer amplifier. The amplifier's harmonic distortion performance now becomes as important as its noise, CMRR linearity, and settling behavior. Few manufacturers specify amplifier THD in the noninverting configuration. These specifications, when available, seldom address signals greater than 10 V p–p or at frequencies above 1 kHz. It may be necessary to characterize candidate amplifiers from several vendors to find the best fit to the particular amplitude and frequency requirements of a particular application. Such evaluations are easily performed using a spectrum analyzer. A notch filter tuned to the fundamental frequency greatly improves measurement resolution. It is also possible to use the AD1382 as the measuring device by performing FFTs on the output data. Refer to the discussion of signal sources in *Testing the AD1382*.

Unipolar Operation

The AD1382 does not provide a direct unipolar input capability. Unipolar inputs can be achieved using the circuits of Figures 19 and 20. The circuit in Figure 19 is suitable when a low input impedance is acceptable. Multiplexed applications should use the circuit of Figure 20. The discussions under High Impedance Inputs also apply to amplifier selection for unipolar operation.

Data Bus Interface

The AD1382's data outputs are CMOS 4 mA drivers and are not intended to be connected directly to a system data bus. Charging and discharging a capacitive data bus creates large supply transients and ground spikes which can interfere with the AD1382's operation and result in erroneous data. Registers and/or buffers should be used to isolate the AD1382 from the bus. Buffering devices should be located close to the AD1382 to minimize the capacitive load presented to the converter's data outputs. Control will be simplified by permanently grounding the AD1382's $\overline{OE}$ input when using buffers. A schematic of a typical 16-bit bus interface is shown in Figure 21.

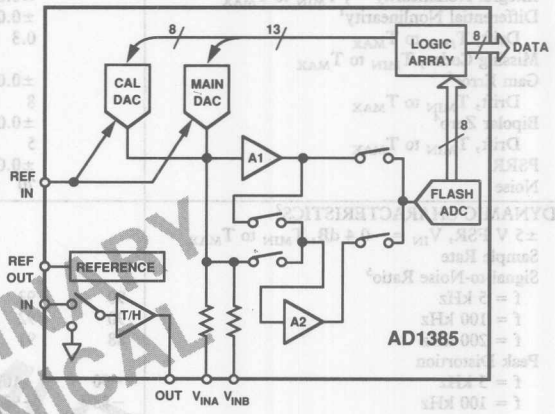
16-Bit 500 kHz Wide Temperature Range Sampling ADC

AD1385



PRODUCT FEATURES

16-Bit Resolution
500 kHz Sampling Rate
Differential Linearity Autocalibration
Specified over −55°C to +125°C Range
SNR 90 dB @ 100 kHz (min)
THD −88 dB @ 100 kHz (min)
0.0006% FSR DNL (typ)
0.0015% FSR INL (typ)
±5, ±10 V Bipolar Input Ranges
Zero Offset Autocalibration

APPLICATIONS

Medical Imaging
CAT
Magnetic Resonance
Radar
Vibration Analysis
Parametric Measurement Unit (ATE)
Digital Storage Oscilloscopes
Waveform Recorders
Analytical Instruments

FUNCTIONAL BLOCK DIAGRAM

PRELIMINARY TECHNICAL DATA

PRODUCT DESCRIPTION

The AD1385 is a complete 500 kHz, 16-bit, sampling analog-to-digital converter contained in a single package. Its differential linearity autocalibration feature allows this high resolution, high speed converter to offer outstanding noise and distortion performance, as well as excellent INL and DNL specifications, over the full military temperature range. Autocalibration effectively eliminates DNL drift over temperature.

The AD1385 architecture includes a low noise, low distortion track/hold, a three pass digitally corrected subranging ADC, and linearity calibration circuitry. A complete linearity calibration requires only 15 ms. Precision thin-film resistors and a proprietary DAC contribute to the part's outstanding dynamic and static performance.

The AD1385 uses four power supplies, ±5 V and ±15 V, and an external 10 MHz clock. Power dissipation is nominally 2.76 W. Two user selectable bipolar input ranges, ±5 V and ±10 V, are provided. Careful attention to grounding and a single package make it easy to design PCBs to achieve specified performance.

The AD1385's pinout is nearly identical to that of the AD1382. Just two additional connections, to enable and monitor autocalibration, are required. This commonality provides an easy upgrade path to extend system performance and operating temperature range.

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

PRELIMINARY TECHNICAL DATA

NOTES
[1]Integral linearity is inferred from FFTs. Differential linearity is derived from histograms.
[2]Performance over temperature is specified within ±15°C of the temperature at which the last calibration was performed.
[3]FSR = Full-Scale Range.
[4]Adjustable to zero.
[5]SNR excludes harmonics 2–9 of the fundamental.
[6]THD includes harmonics 2–9 of the fundamental.
[7]Refer to Figures 17, 18 and 24. Guaranteed over operating temperature range, not 100% production tested.
[8]Aperture delay is the time from the rising edge on the Hold Command Input to the opening of the switch in the Track/Hold.
Specifications subject to change without notice.

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

$-V_S$ to AGND	−18 V
V_{DD} to PGND	7 V
V_{SS} to PGND	−7 V
AGND to PGND	±0.3 V
Analog Inputs	$\pm V_S$
Reference Input	0 V to +11 V
Digital Inputs	−0.3 V to V_{DD} + 0.3 V
Output Short Circuit Duration	
Reference Output	Indefinite
Track/Hold Output	1 sec
Digital Outputs	1 sec for Any One Output
Case Temperature (Operating)	−55°C to +125°C
Storage Temperature	−65°C to +150°C

*Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Complete 12-Bit 1.25 MSPS Monolithic A/D Converter

AD1671

FEATURES

Conversion Time: 800 ns
1.25 MHz Throughput Rate
Complete: On-Chip Sample-and-Hold Amplifier and Voltage Reference
Low Power Dissipation: 570 mW
No Missing Codes Guaranteed
Signal-to-Noise Plus Distortion Ratio
f_{IN} = 100 kHz: 69 dB Minimum
Pin Configurable Input Voltage Ranges
Twos Complement or Offset Binary Output Data
28-Pin DIP or 28-Pin Surface Mount Package
Out of Range Indicator

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD1671 is a monolithic 12-bit, 1.25 MSPS analog-to-digital converter with an on-board, high performance sample-and-hold amplifier (SHA) and voltage reference. The AD1671 guarantees no missing codes over the full operating temperature range. The combination of a merged high speed bipolar/CMOS process and a novel architecture results in a combination of speed and power consumption far superior to previously available hybrid implementations. Additionally, the greater reliability of monolithic construction offers improved system reliability and lower costs than hybrid designs.

The fast settling input SHA is equally suited for both multiplexed systems that switch negative to positive full-scale voltage levels in successive channels and sampling inputs at frequencies up to and beyond the Nyquist rate. The AD1671 provides both reference output and reference input pins, allowing the on-board reference to serve as a system reference. An external reference can also be chosen to suit the dc accuracy and temperature drift requirements of the application.

The AD1671 uses a subranging flash conversion technique, with digital error correction for possible errors introduced in the first part of the conversion cycle. An on-chip timing generator provides strobe pulses for each of the four internal flash cycles. A single ENCODE pulse is used to control the converter. The digital output data is presented in twos complement or offset binary output format. An out-of-range signal indicates an overflow condition. It can be used with the most significant bit to determine low or high overflow.

The performance of the AD1671 is made possible by using high speed, low noise bipolar circuitry in the linear sections and low power CMOS for the logic sections. Analog Devices' ABCMOS-1 process provides both high speed bipolar and 2-micron CMOS devices on a single chip. Laser trimmed thin-film resistors are used to provide accuracy and temperature stability.

The AD1671 is available in two performance grades and three temperature ranges. The AD1671J and K grades are available over the 0°C to +70°C temperature range. The AD1671A grade is available over the −40°C to +85°C temperature range. The AD1671S grade is available over the −55°C to +125°C temperature range.

PRODUCT HIGHLIGHTS

The AD1671 offers a complete single chip sampling 12-bit, 1.25 MSPS analog-to-digital conversion function in a 28-pin package.

The AD1671 at 570 mW consumes a fraction of the power of currently available hybrids.

An OUT OF RANGE output bit indicates when the input signal is beyond the AD1671's input range.

Input signal ranges are 0 V to +5 V unipolar or ±5 V bipolar, selected by pin strapping, with an input resistance of 10 kΩ. The input signal range can also be pin strapped for 0 V to +2.5 V unipolar or ±2.5 V bipolar with an input resistance of 10 MΩ.

Output data is available in unipolar, bipolar offset or bipolar twos complement binary format.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Symbol	Pin No.	Type	Name and Function
ACOM	27	P	Analog Ground.
AIN	22, 23	AI	Analog Inputs, AIN1 and AIN2. The AD1671 can be pin strapped for four input ranges: Range — Pin Strap — Signal Input 0 to +2.5 V, ±2.5 V — Connect AIN1 to AIN2 — AIN1 or AIN2 0 to +5 V, ±5 V — Connect AIN1 or AIN2 to ACOM — AIN1 or AIN2
BIT 1 (MSB)	13	DO	Most Significant Bit.
BIT 2–BIT 11	12–3	DO	Data Bits 2 through 11.
BIT 12 (LSB)	2	DO	Least Significant Bit.
BPO/UPO	26	AI	Bipolar or Unipolar Configuration Pin. See section on Input Range Connections for details.
DAV	16	DO	Data Available Output. The rising edge of DAV indicates an end of conversion and can be used to latch current data into an external register. The falling edge of DAV can be used to latch previous data into an external register.
DCOM	19	P	Digital Ground.
ENCODE	17	DI	The analog input is sampled on the rising edge of ENCODE.
$\overline{MSB}$	14	DO	Inverted Most Significant Bit. Provides twos complement output data format.
OTR	15	DO	Out of Range is Active HIGH when the analog input is out of range. See Output Data Format, Table III.
REF COM	20	AI	REF COM is the internal reference ground pin. REF COM should be connected as indicated in the Grounding and Decoupling Rules and Optional External Reference Connection Sections.
REF IN	24	AI	REF IN is the external 2.5 V reference input.
REF OUT	21	AO	REF OUT is the internal 2.5 V reference output.
SHA OUT	25	AO	No Connect for bipolar input ranges. Connect SHA OUT to BPO/UPO for unipolar input ranges.
V_{CC}	28	P	+5 V Analog Power.
V_{EE}	1	P	−5 V Analog Power.
V_{LOGIC}	18	P	+5 V Digital Power.

TYPE: AI = Analog Input; AO = Analog Output; DI = Digital Input; DO = Digital Output; P = Power.

PRELIMINARY TECHNICAL DATA

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

ABSOLUTE MAXIMUM RATINGS*

Parameter	With Respect to	Min	Max	Units
V_{CC}	ACOM	−0.5	+6.5	Volts
V_{EE}	ACOM	−6.5	+0.5	Volts
V_{LOGIC}	DCOM	−6.5	+0.5	Volts
ACOM	DCOM	−1.0	+1.0	Volts
V_{CC}	V_{LOGIC}	−6.5	+6.5	Volts
ENCODE	DCOM	−0.5	V_{LOGIC}+0.5	Volts
REF IN	ACOM			
AIN	ACOM			
BPO/UPO	ACOM			
Junction Temperature			+150	°C
Storage Temperature		−65	+150	°C
Lead Temperature (10 sec)			+300	°C

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum ratings for extended periods may effect device reliability.

ORDERING GUIDE

Model[1]	Linearity	Temperature Range	Package Option[2]
AD1671JN	±2 LSB	0°C to +70°C	N-28
AD1671KN	±1 LSB	0°C to +70°C	N-28
AD1671AQ	±2 LSB	−40°C to +85°C	Q-28
AD1671SQ	±2 LSB	−55°C to +125°C	Q-28

NOTES
[1]For details on grade and package offerings screened in accordance with MIL-STD-883, refer to Analog Devices' Military Products Databook or current AD1671/883 data sheet.
[2]N = Plastic DIP; Q = Cerdip. For outline information see Package Information section.

PRELIMINARY TECHNICAL DATA

DEFINITIONS OF SPECIFICATIONS

INTEGRAL NONLINEARITY (INL)
Integral nonlinearity refers to the deviation of each individual code from a line drawn from "zero" through "full scale." The point used as "zero" occurs 1/2 LSB (1.22 mV for a 10 V span) before the first code transition (all zeros to only the LSB on). "Full-scale" is defined as a level 1 1/2 LSB beyond the last code transition (to all ones). The deviation is measured from the low side transition of each particular code to the true straight line.

DIFFERENTIAL LINEARITY ERROR (NO MISSING CODES)
An ideal ADC exhibits code transitions that are exactly 1 LSB apart. DNL is the deviation from the ideal value. Thus every code has a finite width. Guaranteed no missing codes to 11 or 12-bit resolution indicates that all 2048 and 4096 codes, respectively, must be present over all operating ranges. No missing codes to 11 bits (in the case of a 12-bit resolution ADC) also means that no two consecutive codes are missing.

UNIPOLAR OFFSET
The first transition should occur at a level 1/2 LSB above analog common. Unipolar offset is defined as the deviation of the actual from that point. This offset can be adjusted as discussed later. The unipolar offset temperature coefficient specifies the maximum change of the transition point over temperature, with or without external adjustments.

BIPOLAR ZERO
In the bipolar mode the major carry transition (0111 1111 1111 to 1000 0000 0000) should occur for an analog value 1/2 LSB below analog common. The bipolar offset error and temperature coefficient specify the initial deviation and maximum change in the error over temperature.

GAIN ERROR
The last transition (from 1111 1111 1110 to 1111 1111 1111) should occur for an analog value 1 1/2 LSB below the nominal full scale (4.9963 volts for 5.000 volts full scale). The gain error is the deviation of the actual level at the last transition from the ideal level. The gain error can be adjusted to zero as shown in Figures 4 through 7.

TEMPERATURE COEFFICIENTS
The temperature coefficients for unipolar offset, bipolar zero and gain error specify the maximum change from the initial (+25°C) value to the value at T_{MIN} or T_{MAX}.

POWER SUPPLY REJECTION
One of the effects of power supply error on the performance of the device will be a small change in gain. The specifications show the maximum full-scale change from the initial value with the supplies at the various limits.

DYNAMIC SPECIFICATIONS

SIGNAL-TO-NOISE PLUS DISTORTION (S/N+D) RATIO
S/N+D is the ratio of the rms value of the measured input signal to the rms sum of all other spectral components, including harmonics but excluding dc. The value for S/N+D is expressed in decibels.

EFFECTIVE NUMBER OF BITS (ENOB)
ENOB is calculated from the expression SNR = 6 .02N + 1.76 dB, where N is equal to the effective number of bits.

TOTAL HARMONIC DISTORTION (THD)
THD is the ratio of the rms sum of the first six harmonic components to the rms value of the measured input signal and is expressed as a percentage or in decibels.

INTERMODULATION DISTORTION (IMD)
With inputs consisting of sine waves at two frequencies, fa and fb, any device with nonlinearities will create distortion products of order (m+n), at sum and difference frequencies of mfa ± nfb, where m, n = 0, 1, 2, 3 . . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are (fa + fb) and (fa − fb), and the third order terms are (2 fa + fb), (2 fa − fb), (fa + 2 fb) and (2fb − fa). The IMD products are expressed as the decibel ratio of the rms sum of the measured input signals to the rms sum of the distortion terms. The two signals are of equal amplitude and the peak value of their sum is −0.5 dB from full scale. The IMD products are normalized to a 0 dB input signal.

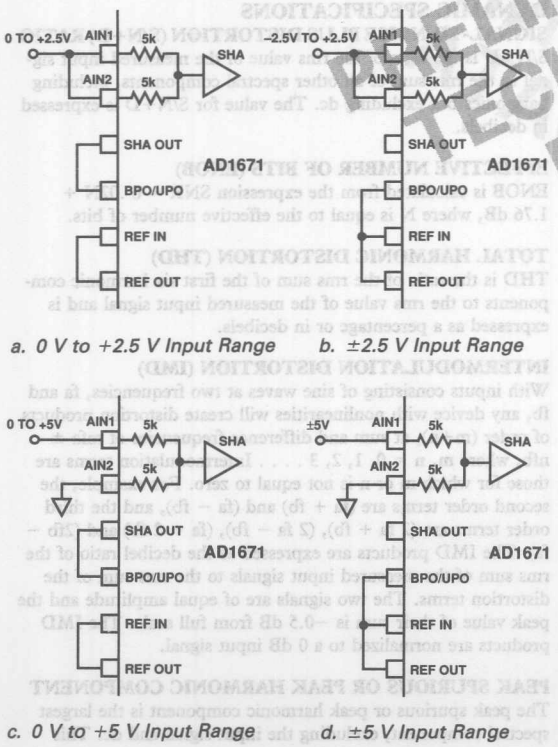
PEAK SPURIOUS OR PEAK HARMONIC COMPONENT
The peak spurious or peak harmonic component is the largest spectral component, excluding the input signal and dc. This value is expressed in decibels relative to the rms value of a full-scale input signal.

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

APERTURE DELAY

Aperture delay is the difference between the switch delay and the analog delay of the SHA. This delay represents the point in time, relative to the rising edge of ENCODE input, that the analog input is sampled.

APERTURE JITTER



Aperture jitter is the variation in aperture delay for successive samples.

THEORY OF OPERATION

The AD1671 uses a successive subranging architecture. The analog-to-digital conversion takes place in four independent steps or flashes. The sampled analog input signal is subranged to an intermediate residue voltage for the final 12-bit result by utilizing multiple flashes with subtraction DACs (see the AD1671 functional block diagram).

The AD1671 can be configured to operate with unipolar (0 V to +5 V, 0 V to +2.5 V) or bipolar (±5 V, ±2.5 V) inputs by connecting AIN (Pins 22, 23), SHA OUT (Pin 25) and BPO/UPO (Pin 26) as shown in Figure 2.

The AD1671 conversion cycle begins by simply providing an active HIGH level on the ENCODE pin (Pin 17). The rising edge of the ENCODE pulse starts the conversion. The falling edge of the ENCODE pulse is specified to operate within a window of time, less than 50 ns after the rising edge of ENCODE or after the falling edge of DAV. The time window prevents digitally coupled noise from being introduced during the final stages of conversion. An internal timing generator circuit accurately controls SHA, flash and DAC timing.

a. 0 V to +2.5 V Input Range b. ±2.5 V Input Range

c. 0 V to +5 V Input Range d. ±5 V Input Range

Figure 2. AD1671 Input Range Connections

Upon receipt of an ENCODE command the input voltage is held by the front-end SHA and the first 3-bit flash converts the analog input voltage. The 3-bit result is passed to a correction logic register and a segmented current output DAC. The DAC output is connected through a resistor (within the Range/Span Select Block) to SHA OUT. A residue voltage is created by subtracting the DAC output from SHA OUT, which is less than one eighth of the full-scale analog input. The second flash has an input range that is configured with one bit of overlap with the previous DAC. The overlap allows for errors during the flash conversion. The first residue voltage is connected to the second 3-bit flash and to the noninverting input of a high speed, differential, gain of eight amplifier. The second flash result is passed to the correction logic register and to the second segmented current output DAC. The output of the second DAC is connected to the inverting input of the differential amplifier. The differential amplifier output is connected to a two-step, backend, 8-bit flash. This 8-bit flash consists of coarse and fine flash converters. The result of the coarse 4-bit flash converter, also configured to overlap one bit of DAC 2, is connected to the correction logic register and selects one of 16 resistors from which the fine 4-bit flash will establish its span voltage. The fine 4-bit flash is connected directly to the output latches.

The internal timing generator automatically places the SHA into the acquire mode when DAV goes LOW. Upon completion of conversion (when DAV is set HIGH), the SHA has acquired the analog input to the specified level of accuracy and will remain in the sample mode until the next ENCODE command.

The AD1671 will flag an out-of-range condition when the input voltage exceeds the analog input range. OTR (Pin 15) is active HIGH when an out-of-range high or low condition exists. Bits 1–12 are HIGH when the analog input voltage is greater than the selected input range and LOW when the analog input is less than the selected input range.

APPLYING THE AD1671

GROUNDING AND DECOUPLING RULES

Proper grounding and decoupling should be a primary design objective in any high speed, high resolution system. The AD1671 separates analog and digital grounds to optimize the management of analog and digital ground currents in a system. The AD1671 is designed to minimize the current flowing from REF COM (Pin 20) by directing the majority of the current from V_{CC} (+5 V–Pin 28) to V_{EE} (−5 V–Pin 1). Minimizing analog ground currents hence reduces the potential for large ground voltage drops. This can be especially true in systems that do not utilize ground planes or wide ground runs. REF COM is also configured to be code independent, therefore reducing input dependent analog ground voltage drops and errors. Code dependent ground current is diverted to ACOM (Pin 27). Also critical in any high speed digital design is the use of proper digital grounding techniques to avoid potential CMOS "ground bounce." Figure 3 is provided to assist in the proper layout, grounding and decoupling techniques.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

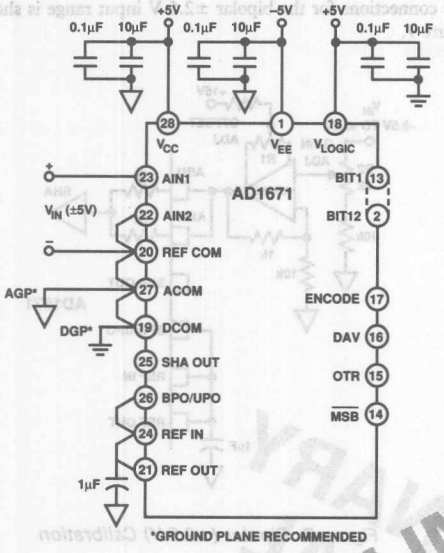


Figure 3. AD1671 Grounding and Decoupling

Table I is a list of grounding and decoupling rules that should be reviewed before laying out a printed circuit board.

Table I. Grounding and Decoupling Guidelines

Power Supply Decoupling	**Comment**
Capacitor Values	0.1 µF (Ceramic) and 1 µF (Tantalum) Surface Mount Chip Capacitors Recommended to Reduce Lead Inductance
Capacitor Locations	Directly at Positive and Negative Supply Pins to Common Ground Plane
Reference (REF OUT)	
Capacitor Value	1 µF (Tantalum) to ACOM
Grounding	
Analog Ground	Ground Plane or Wide Ground Return Connected to the Analog Power Supply
Reference Ground (REF COM)	Critical Common Connections Should be Star Connected to REF COM (as Shown in Figure 3)
Digital Ground	Ground Plane or Wide Ground Return Connected to the Digital Power Supply
Analog and Digital Ground	Connected Together Once at the AD1671

PRELIMINARY TECHNICAL DATA

UNIPOLAR (0 V TO +5 V) CALIBRATION

The AD1671 is factory trimmed to minimize offset, gain and linearity errors. In some applications the offset and gain errors of the AD1671 need to be externally adjusted to zero. This is accomplished by trimming the voltage at AIN2 (Pin 22). The circuit in Figure 4 is recommended for calibrating offset and gain errors of the AD1671 when configured in the 0 V to +5 V input range. If the offset trim resistor R1 is used, it should be trimmed as follows, although a different offset can be set for a particular system requirement. This circuit will give approximately ±5 mV of offset trim range. Nominally the AD1671 is intended to have a 1/2 LSB offset so that the exact analog input for a given code will be in the middle of that code (halfway between the transitions to the codes above it and below it). Thus, the first transition (from 0000 0000 0000 to 0000 0000 0001) will occur for an input level of +1/2 LSB (0.61 mV for 5 V range).

The gain trim is done by applying a signal 1 1/2 LSBs below the nominal full scale (4.998 for a 5 V range). Trim R2 to give the last transition (1111 1111 1110 to 1111 1111 1111). This circuit will give approximately ±0.5% FS of adjustment range.

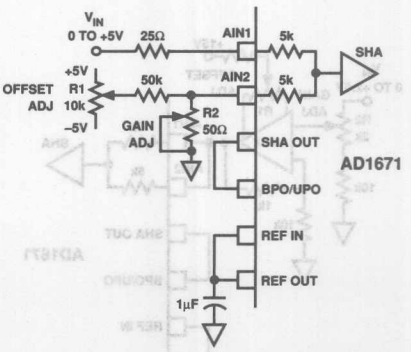

Figure 4. Unipolar (0 V to +5 V) Calibration

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

BIPOLAR (±5 V) CALIBRATION

The connections for the bipolar ±5 V input range is shown in Figure 5.

Bipolar calibration is similar to unipolar calibration. First, a signal 1/2 LSB above negative full scale (−4.9988 V) is applied and R1 is trimmed to give the first transition (0000 0000 0000 to 0000 0000 0001). Then a signal 1 1/2 LSB below positive full scale (+4.9963 V) is applied and R2 is trimmed to give the last transition (1111 1111 1110 to 1111 1111 1111).

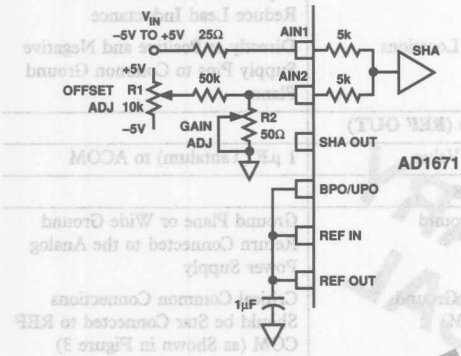

Figure 5. Bipolar (±5 V) Calibration

UNIPOLAR (0 V TO +2.5 V) CALIBRATION

The connections for the 0 V to +2.5 V input range calibration is shown in Figure 6. Figure 6 shows an example of how the offset error can be trimmed in front of the AD1671. The procedure for trimming the offset and gain errors is the same as for the unipolar 5 V range.

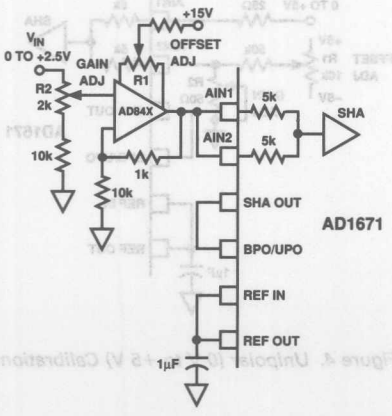

Figure 6. Unipolar (0 V to +2.5 V) Calibration

BIPOLAR (±2.5 V) CALIBRATION

The connections for the bipolar ±2.5 V input range is shown in Figure 7.

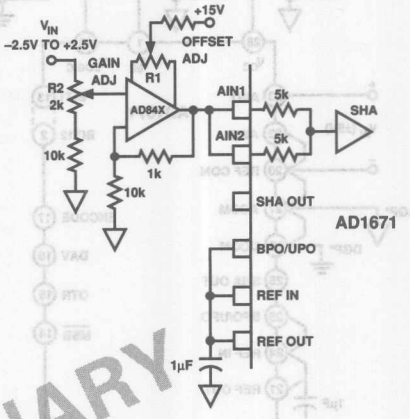

Figure 7. Bipolar (±2.5 V) Calibration

OUTPUT LATCHES

Figure 8 shows the AD1671 connected to the 74HC574 octal D-type edge-triggered latches with 3-state outputs. The latch can drive highly capacitive loads (i.e., bus lines, I/O ports) while maintaining the data signal integrity. The maximum setup and hold times of the 574 type latch must be less than 20 ns (t_{DD} and t_{SS} minimum). To satisfy the requirements of the 574 type latch the recommended logic families are S, AS, ALS, F or BCT. New data from the AD1671 is latched on the rising edge of the DAV (Pin 16) output pulse. Previous data can be latched by inverting the DAV output with a 7404 type inverter.

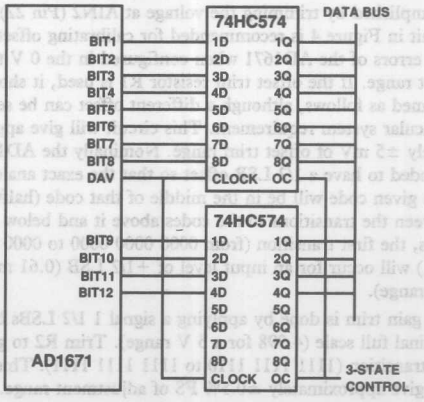

Figure 8. AD1671 to Output Latches

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

OUT OF RANGE

An out-of-range condition exists when the analog input voltage is beyond the input range (0 V to +2.5 V, 0 V to +5 V, ±2.5 V, ±5 V) of the converter. OTR (Pin 15) is set low when the analog input voltage is within the analog input range. OTR is set HIGH and will remain HIGH when the analog input voltage exceeds the input range by typically 1/2 LSB (OTR transition is tested to ±6 LSBs of accuracy) from the center of the ±full-scale output codes. OTR will remain HIGH until the analog input is within the input range and another conversion is completed. By logical ANDing OTR with the MSB and its complement, overrange high or underrange low conditions can be detected. Table II is a truth table for the over/under range circuit in Figure 9. Systems requiring programmable gain conditioning prior to the AD1671 can immediately detect an out-of-range condition, thus eliminating gain selection iterations.

Table II. Out-of-Range Truth Table

OTR	MSB	Analog Input Is
0	0	In Range
0	1	In Range
1	0	Underrange
1	1	Overrange

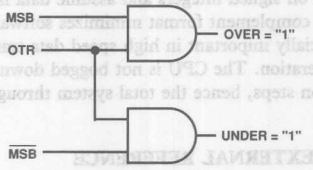

Figure 9. Overrange or Underrange Logic

Table III. Output Data Format

[2]Typical performance.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

The AD1671 provides both MSB and $\overline{MSB}$ outputs, delivering data in positive true straight binary for unipolar input ranges and positive true offset binary or twos complement for bipolar input ranges. Straight binary coding is used for systems that accept positive-only signals. If straight binary coding is used with bipolar input signals, a 0 V input would result in a binary output of 2048. The application software would have to subtract 2048 to determine the true input voltage. Host registers typically perform math on signed integers and assume data is in that format. Twos complement format minimizes software overhead which is especially important in high speed data transfers, such as a DMA operation. The CPU is not bogged down performing data conversion steps, hence the total system throughput is increased.

OPTIONAL EXTERNAL REFERENCE

The AD1671 includes an on-board +2.5 V reference. The reference input pin (REF IN) can be connected to reference output pin (REF OUT) or a standard external +2.5 V reference can be selected to meet specific system requirements. Fast switching input dependent currents are modulated at the reference input. The reference input voltage can be held with the use of a capacitor. To prevent the AD1671's on-board reference from oscillating when not connected to REF IN, REF OUT must be connected to analog ground. Connecting REF OUT to analog ground, due to its output circuit implementation shuts down the reference output.

Figure 10 is the typical logic supply current vs. conversion rate for various capacitor loads.

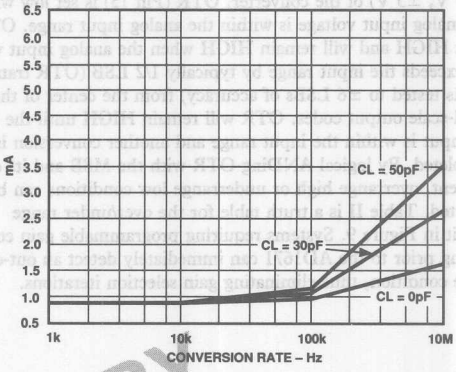

Figure 10. I_{LOGIC} vs. Conversion Rate for Various Capacitive Loads on the Digital Outputs

12-Bit 100 kSPS A/D Converter

AD1674*

FEATURES

- Complete Monolithic 12-Bit 10 μs Sampling ADC
- On-Board Sample-and-Hold Amplifier
- Industry Standard Pinout
- 8- and 16-Bit Microprocessor Interface
- AC and DC Specified and Tested
- Unipolar and Bipolar Inputs
- ±5 V, ±10 V, 0–10 V, 0–20 V Input Ranges
- Commercial, Industrial and Military Temperature Range Grades
- MIL-STD-883 Compliant Versions Available

FUNCTIONAL BLOCK DIAGRAM

PRODUCT DESCRIPTION

The AD1674 is a complete, multipurpose, 12-bit analog-to-digital converter, consisting of a user-transparent on-board sample-and-hold amplifier (SHA), 10 volt reference, clock and three-state output buffers for microprocessor interface.

The AD1674 is pin compatible with the industry standard AD574A and AD674A, but includes a sampling function while delivering a faster conversion rate. The on-chip SHA has a wide input bandwidth supporting 12-bit accuracy over the full Nyquist bandwidth of the converter.

The AD1674 is fully specified for ac parameters (such as S/(N+D) ratio, THD, and IMD) and dc parameters (offset, full-scale error, etc.). With both ac and dc specifications, the AD1674 is ideal for use in signal processing and traditional dc measurement applications.

The AD1674 design is implemented using Analog Devices' BiMOS II process allowing high performance bipolar analog circuitry to be combined on the same die with digital CMOS logic.

Five different grades are available. The AD1674J and K grades are specified for operation over the 0°C to +70°C temperature range. The A and B grades are specified from −40°C to +85°C; the AD1674T grade is specified from −55°C to +125°C. The J and K grades are available in a 28-pin plastic DIP or 28-lead SOIC. All other grades are available in a 28-pin hermetically sealed ceramic DIP.

PRODUCT HIGHLIGHTS

1. Industry Standard Pinout: The AD1674 utilizes the pinout established by the industry standard AD574A and AD674A. In stand-alone mode, the AD1674 has identical interface requirements as the AD574A and AD674A. In full control mode, the AD1674 requires slight control timing modification.
2. Integrated SHA: The AD1674 has an integrated SHA which supports the full Nyquist bandwidth of the converter. The SHA function is transparent to the user; no wait-states are needed for SHA acquisition.
3. DC and AC Specified: In addition to traditional dc specifications, the AD1674 is also fully specified for frequency domain ac parameters such as total harmonic distortion, signal-to-noise ratio and input bandwidth. These parameters can be tested and guaranteed as a result of the on-board SHA.
4. Analog Operation: The precision, laser-trimmed scaling and bipolar offset resistors provide four calibrated ranges: 0 to +10 V and 0 to +20 V unipolar, −5 V to +5 V and −10 V to +10 V bipolar. The AD1674 operates on +5 V and ±12 V or ±15 V power supplies.
5. Flexible Digital Interface: On-chip multiple-mode three-state output buffers and interface logic allow direct connection to most microprocessors.

*Protected by U. S. Patent Nos. 4,962,325; 4,250,445; 4,808,908; RE30586.

High R/$\overline{C}$ Pulse Width	t_{HRH}	150			ns

NOTE
Specifications shown in **boldface** are tested on all devices at final electrical test with worst case supply voltages at T_{min}, 25°C, and T_{max}. Results from those tests are used to calculate outgoing quality levels. All min and max specifications are guaranteed, although only those shown in boldface are tested.

Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS*

V_{CC} to Digital Common . . . . . 0 to +16.5 V
V_{EE} to Digital Common . . . . . 0 to −16.5 V
V_{LOGIC} to Digital Common . . . . . 0 to +7 V
Analog Common to Digital Common . . . . . ±1 V
Digital Inputs to Digital Common . −0.5 V to V_{LOGIC} +0.5 V
Analog Inputs to Analog Common . . . . . V_{EE} to V_{CC}
20 V_{IN} to Analog Common . . . . . ±24 V
REF OUT . . . . . Indefinite Short to Common
. . . . . Momentary Short to V_{CC}
Junction Temperature . . . . . +175°C
Power Dissipation . . . . . 825 mW
Lead Temperature, Soldering . . . . . 300°C, 10 sec
Storage Temperature . . . . . −65°C to +150°C

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

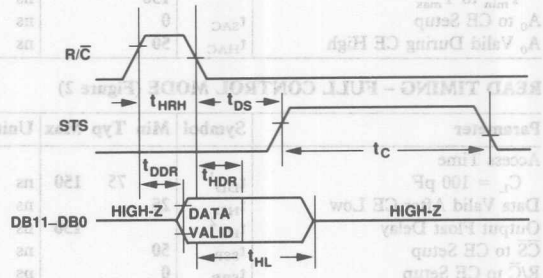

Figure 4b. Stand-Alone Mode Timing High Pulse for R/$\overline{C}$

CAUTION:
ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

ORDERING GUIDE

Model[1]	Temperature Range	INL (T_{min} to T_{max})	S/(N+D) (T_{min} to T_{max})	Package Option[2]
AD1674JN	0°C to +70°C	±1 LSB	69 dB	N-28A
AD1674KN	0°C to +70°C	±1/2 LSB	70 dB	N-28A
AD1674JR	0°C to +70°C	±1 LSB	69 dB	R-28
AD1674KR	0°C to +70°C	±1/2 LSB	70 dB	R-28
AD1674AD	−40°C to +85°C	±1 LSB	69 dB	D-28A
AD1674BD	−40°C to +85°C	±1/2 LSB	70 dB	D-28A
AD1674TD	−55°C to +125°C	±1 LSB	70 dB	D-28A

NOTES

DEFINITION OF SPECIFICATIONS

INTEGRAL NONLINEARITY (INL)

The ideal transfer function for an ADC is a straight line drawn between "zero" and "full scale." The point used as "zero" occurs 1/2 LSB before the first code transition. "Full scale" is defined as a level 1 1/2 LSB beyond the last code transition. Integral nonlinearity is the worst-case deviation of a code from the straight line. The deviation of each code is measured from the middle of that code.

DIFFERENTIAL NONLINEARITY (DNL)

A specification which guarantees no missing codes requires that every code combination appear in a monotonic increasing sequence as the analog input level is increased. Thus every code must have a finite width. The AD1674 guarantees no missing codes to 12-bit resolution; all 4096 codes are present over the entire operating range.

UNIPOLAR OFFSET

The first transition should occur at a level 1/2 LSB above analog common. Unipolar offset is defined as the deviation of the actual transition from that point at 25°C. This offset can be adjusted as shown in Figure 6.

BIPOLAR OFFSET

In the bipolar mode the major carry transition (0111 1111 1111 to 1000 0000 0000) should occur for an analog value 1/2 LSB below analog common. The bipolar offset error specifies the deviation of the actual transition from that point at 25°C. This offset can be adjusted as shown in Figure 7.

FULL-SCALE ERROR

The last transition (from 1111 1111 1110 to 1111 1111 1111) should occur for an analog value 1 1/2 LSB below the nominal full scale (9.9963 volts for 10 volts full scale). The full-scale error is the deviation of the actual level of the last transition from the ideal level at 25°C. The full-scale error can be adjusted to zero as shown in Figures 6 and 7.

TEMPERATURE DRIFT

The temperature drifts for full-scale error, unipolar offset and bipolar offset specify the maximum change from the initial (25°C) value to the value at T_{min} or T_{max}.

POWER SUPPLY REJECTION

The effect of power supply error on the performance of the device will be a small change in full scale. The specifications show the maximum full-scale change from the initial value with the supplies at various limits.

FREQUENCY-DOMAIN TESTING

The AD1674 is tested dynamically using a sine wave input and a 2048 point Fast Fourier Transform (FFT) to analyze the resulting output. Coherent sampling is used, wherein the ADC sampling frequency and the analog input frequency are related to each other by a ratio of integers. This ensures that an integral multiple of input cycles is captured, allowing direct FFT processing without windowing or digital filtering which could mask some of the dynamic characteristics of the device. In addition, the frequencies are chosen to be "relatively prime" (no common factors) to maximize the number of different ADC codes that are present in a sample sequence. The result, called Prime Coherent Sampling, is a highly accurate and repeatable measure of the actual frequency-domain response of the converter.

NYQUIST FREQUENCY

An implication of the Nyquist sampling theorem, the "Nyquist Frequency" of a converter is that input frequency which is one-half the sampling frequency of the converter.

SIGNAL-TO-NOISE AND DISTORTION (S/N+D) RATIO

S/(N+D) is the ratio of the rms value of the measured input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc. The value for S/(N+D) is expressed in decibels.

TOTAL HARMONIC DISTORTION (THD)

THD is the ratio of the rms sum of the first six harmonic components to the rms value of a full-scale input signal and is expressed as a percentage or in decibels. For input signals or harmonics that are above the Nyquist frequency, the aliased component is used.

INTERMODULATION DISTORTION (IMD)

With inputs consisting of sine waves at two frequencies, fa and fb, any device with nonlinearities will create distortion products, of order (m+n), at sum and difference frequencies of mfa ± nfb, where m,n = 0,1,2,3... Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are (fa + fb) and (fa − fb) and the third order terms are (2fa + fb), (2fa − fb), (fa + 2fb) and (fa − 2fb). The IMD products are expressed as the decibel ratio of the rms sum of the measured input signals to the rms sum of the distortion terms. The two signals are of equal amplitude and the peak value of their sums is −0.5 dB from full-scale. The IMD products are normalized to a 0 dB input signal.

FULL-POWER BANDWIDTH

The full-power bandwidth is that input frequency at which the amplitude of the reconstructed fundamental is reduced by 3 dB for a full-scale input.

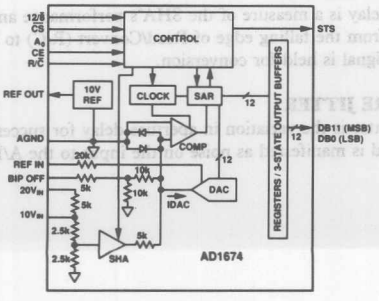
FULL-LINEAR BANDWIDTH

The full-linear bandwidth is the input frequency at which the slew rate limit of the sample-hold-amplifier (SHA) is reached. At this point, the amplitude of the reconstructed fundamental has degraded by less than −0.1 dB. Beyond this frequency, distortion of the sampled input signal increases significantly.

APERTURE DELAY

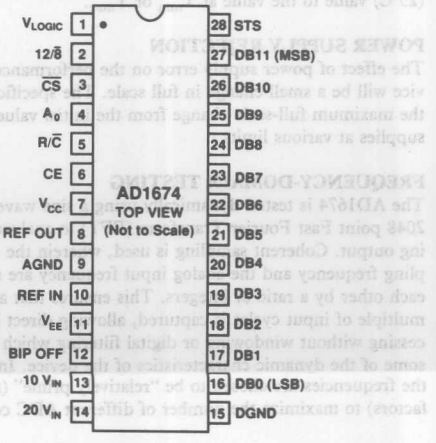
Aperture delay is a measure of the SHA's performance and is measured from the falling edge of Read/Convert (R/$\overline{C}$) to when the input signal is held for conversion.

APERTURE JITTER



Aperture jitter is the variation in aperture delay for successive samples and is manifested as noise on the input to the A/D.

PIN DESCRIPTION



Symbol	Pin No.	Type	Name and Function
AGND	9	P	Analog Ground (Common).
A_0	4	DI	Byte Address/Short Cycle. If a conversion is started with A_0 Active LOW, a full 12-bit conversion cycle is initiated. If A_0 is Active HIGH during a convert start, a shorter 8-bit conversion cycle results. During Read ($R/\overline{C}$ = 1) with $12/\overline{8}$ LOW, A_0 = LOW enables the 8 most significant bits (DB4–DB11), and A_0 = HIGH enables DB3–DB0 and sets DB7–DB4 = 0.
BIP OFF	12	AI	Bipolar Offset. Connect through a 50 Ω resistor to REF OUT for bipolar operation or to Analog Common for unipolar operation.
CE	6	DI	Chip Enable. Chip Enable is Active HIGH and is used to initiate a convert or read operation.
$\overline{CS}$	3	DI	Chip Select. Chip Select is Active LOW.
DB11–DB8	27–24	DO	Data Bits 11 through 8. In the 12-bit format (see $12/\overline{8}$ and A_0 pins), these pins provide the upper 4 bits of data. In the 8-bit format, they provide the upper 4 bits when A_0 is LOW and are disabled when A_0 is HIGH.
DB7–DB4	23–20	DO	Data Bits 7 through 4. In the 12-bit format these pins provide the middle 4 bits of data. In the 8-bit format they provide the middle 4 bits when A_0 is LOW and all zeroes when A_0 is HIGH.
DB3–DB0	19–16	DO	Data Bits 3 through 0. In both the 12-bit and 8-bit format these pins provide the lower 4 bits of data when A_0 is HIGH; they are disabled when A_0 is LOW.
DGND	15	P	Digital Ground (Common).
REF OUT	8	AO	+10 V Reference Output.
$R/\overline{C}$	5	DI	Read/Convert. In the full control mode $R/\overline{C}$ is Active HIGH for a read operation and Active LOW for a convert operation. In the stand-alone mode, the falling edge of $R/\overline{C}$ initiates a conversion.
REF IN	10	AI	Reference Input is connected through a 50 Ω resistor to +10 V Reference for normal operation.
STS	28	DO	Status is Active HIGH when a conversion is in progress and goes LOW when the conversion is completed.
V_{CC}	7	P	+12 V/+15 V Analog Supply.
V_{EE}	11	P	−12 V/−15 V Analog Supply.
V_{LOGIC}	1	P	+5 V Logic Supply.
10 V_{IN}	13	AI	10 V Span Input, 0 to +10 V unipolar mode or −5 V to +5 V bipolar mode. When using the AD1674 in the 20 V Span 10 V_{IN} should not be connected.
20 V_{IN}	14	AI	20 V Span Input, 0 to +20 V unipolar mode or −10 V to +10 V bipolar mode. When using the AD1674 in the 10 V Span 20 V_{IN} should not be connected.
$12/\overline{8}$	2	DI	The $12/\overline{8}$ pin determines whether the digital output data is to be organized as two 8-bit words ($12/\overline{8}$ LOW) or a single 12-bit word ($12/\overline{8}$ HIGH).

FUNCTIONAL BLOCK DIAGRAM

PIN CONFIGURATION

GENERAL CIRCUIT OPERATION

The AD1674 is a complete 12-bit, 10 μs sampling analog-to-digital converter. A block diagram of the AD1674 is shown on the previous page.

When the control section is commanded to initiate a conversion (as described later), it places the sample-and-hold amplifier (SHA) in the hold mode, enables the clock, and resets the successive approximation register (SAR). Once a conversion cycle has begun, it cannot be stopped or restarted and data is not available from the output buffers. The SAR, timed by the clock, will sequence through the conversion cycle and return an end-of-convert flag to the control section when the conversion has been completed. The control section will then disable the clock, switch the SHA to sample mode, and delay the STS LOW going edge to allow for acquisition to 12-bit accuracy. The control section will allow data read functions by external command anytime during the SHA acquisition interval.

During the conversion cycle, the internal 12-bit, 1 mA full-scale current output DAC is sequenced by the SAR from the most significant bit (MSB) to the least significant bit (LSB) to provide an output that accurately balances the current through the 5 kΩ resistor from the input signal voltage held by the SHA. The SHA's input scaling resistors divide the input voltage by 2 for the 10 V input span and by 4 for the 20 V input span, maintaining a 1 mA full-scale output current through the 5 kΩ resistor for both ranges. The comparator determines whether the addition of each successively weighted bit current causes the DAC current sum to be greater than or less than the input current. If the sum is less, the bit is left on; if more, the bit is turned off. After testing all the bits, the SAR contains a 12-bit binary code which accurately represents the input signal to within ±1/2 LSB.

CONTROL LOGIC

The AD1674 may be operated in one of two modes, the full-control mode and the stand-alone mode. The full-control mode utilizes all the AD1674 control signals and is useful in systems that address decode multiple devices on a single data bus. The stand-alone mode is useful in systems with dedicated input ports available and thus not requiring full bus interface capability. Table I is a truth table for the AD1674, and Figure 5 illustrates the internal logic circuitry.

CE	$\overline{CS}$	R/$\overline{C}$	12/$\overline{8}$	A_0	Operation
0	X	X	X	X	None
X	1	X	X	X	None
1	0	0	X	0	Initiate 12-Bit Conversion
1	0	0	X	1	Initiate 8-Bit Conversion
1	0	1	1	X	Enable 12-Bit Parallel Output
1	0	1	0	0	Enable 8 Most Significant Bits
1	0	1	0	1	Enable 4 LSBs +4 Trailing Zeroes

Table I. AD1674A Truth Table

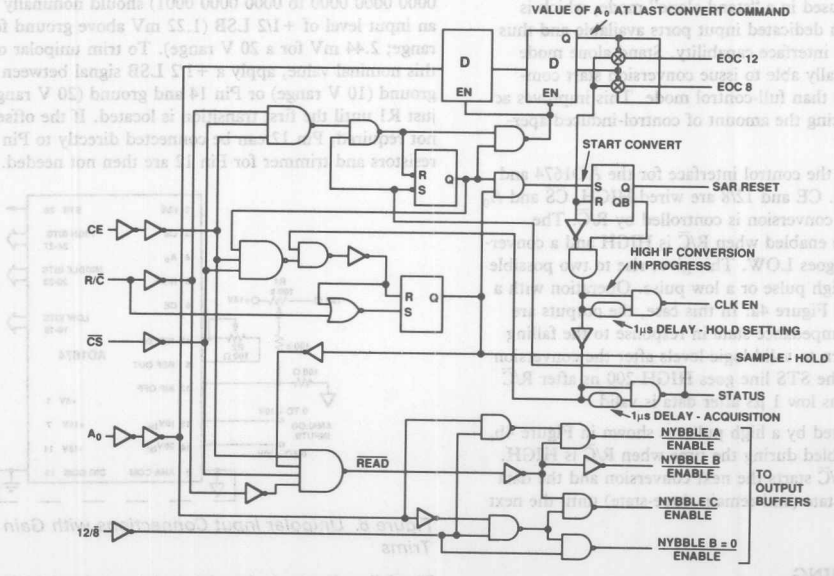

Figure 5. Equivalent Internal Logic Circuitry

FULL-CONTROL MODE

In full-control mode, the AD1674 departs slightly from the AD674A timing requirements. These differences are discussed in Table II. In full-control mode, AD1674 timing should be reviewed for compliancy with AD674A applications.

Specification	AD674A	AD1674
t_{HRC}	50 ns (min)	50 ns @ 25°C 150 ns T_{min} to T_{max}
t_{HRR}	0 ns (min)	60 ns
t_{DSC}	200 ns (max)	200 ns @ 25°C 250 ns T_{min} to T_{max}
t_{HS}	600 ns (max)	1 μs

Table II.

Chip Enable (CE), Chip Select ($\overline{CS}$) and Read/Convert (R/$\overline{C}$) are used to control Convert or Read modes of operation. Either CE or $\overline{CS}$ may be used to initiate a conversion. Note that the shortest delay path to the SHA control is from the R/$\overline{C}$ input (see Figure 5). SHA accuracy has been optimized for use in stand-alone mode and consequently results in the Table II differences for the full-control mode of operation. The state of R/$\overline{C}$ when CE and $\overline{CS}$ are both asserted determines whether a data Read (R/$\overline{C}$ = 1) or a Convert (R/$\overline{C}$ = 0) is in progress. R/$\overline{C}$ should be LOW before both CE and $\overline{CS}$ are asserted; if R/$\overline{C}$ is HIGH, a Read operation will momentarily occur, possibly resulting in system bus contention.

STAND-ALONE MODE

The AD1674 can be used in a "stand-alone" mode, which is useful in systems with dedicated input ports available and thus not requiring full bus interface capability. Stand-alone mode applications are generally able to issue conversion start commands more precisely than full-control mode. This improves ac performance by reducing the amount of control-induced aperture jitter.

In stand-alone mode, the control interface for the AD1674 and AD674A are identical. CE and 12/$\overline{8}$ are wired HIGH, $\overline{CS}$ and A_0 are wired LOW, and conversion is controlled by R/$\overline{C}$. The three-state buffers are enabled when R/$\overline{C}$ is HIGH and a conversion starts when R/$\overline{C}$ goes LOW. This gives rise to two possible control signals — a high pulse or a low pulse. Operation with a low pulse is shown in Figure 4a. In this case, the outputs are forced into the high-impedance state in response to the falling edge of R/$\overline{C}$ and return to valid logic levels after the conversion cycle is completed. The STS line goes HIGH 200 ns after R/$\overline{C}$ goes LOW and returns low 1 μs after data is valid.

If conversion is initiated by a high pulse as shown in Figure 4b, the data lines are enabled during the time when R/$\overline{C}$ is HIGH. The falling edge of R/$\overline{C}$ starts the next conversion and the data lines return to three-state (and remain three-state) until the next high pulse of R/$\overline{C}$.

CONVERSION TIMING

Once a conversion is started, the STS line goes HIGH. Convert start commands will be ignored until the conversion cycle is complete. The output data buffers can be enabled up to 1.2 μs prior to STS going LOW. The STS line will return LOW at the end of the conversion cycle.

The register control inputs, A_0 and 12/$\overline{8}$, control conversion length and data format. If a conversion is started with A_0 LOW, a full 12-bit conversion cycle is initiated. If A_0 is HIGH during a convert start, a shorter 8-bit conversion cycle results.

During data read operations, A_0 determines whether the three-state buffers containing the 8 MSBs of the conversion result (A_0 = 0) or the 4 LSBs (A_0 = 1) are enabled. The 12/$\overline{8}$ pin determines whether the output data is to be organized as two 8-bit words (12/$\overline{8}$ tied LOW) or a single 12-bit word (12/$\overline{8}$ tied HIGH). In the 8-bit mode, the byte addressed when A_0 is high contains the 4 LSBs from the conversion followed by four trailing zeroes. This organization allows the data lines to be overlapped for direct interface to 8-bit buses without the need for external three-state buffers.

INPUT CONNECTIONS AND CALIBRATION

The 10 V p–p and 20 V p–p full-scale input ranges of the AD1674 accept the majority of signal voltages without the need for external voltage divider networks which could deteriorate the accuracy of the ADC.

The AD1674 is factory trimmed to minimize offset, linearity, and full-scale errors. In many applications, no calibration trimming will be required and the AD1674 will exhibit the accuracy limits listed in the specification tables.

In some applications, offset and full-scale errors need to be trimmed out completely. The following sections describe the correct procedure for these various situations.

UNIPOLAR RANGE INPUTS

Figure 6 illustrates the external connections for the AD1674 in unipolar-input mode. The first output-code transition (from 0000 0000 0000 to 0000 0000 0001) should nominally occur for an input level of +1/2 LSB (1.22 mV above ground for a 10 V range; 2.44 mV for a 20 V range). To trim unipolar offset to this nominal value, apply a +1/2 LSB signal between Pin 13 and ground (10 V range) or Pin 14 and ground (20 V range) and adjust R1 until the first transition is located. If the offset trim is not required, Pin 12 can be connected directly to Pin 9; the two resistors and trimmer for Pin 12 are then not needed.

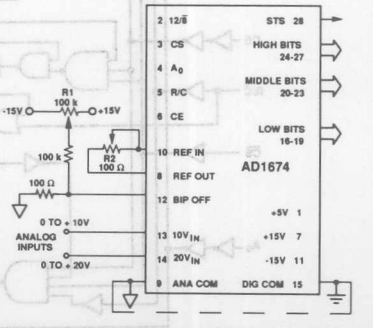

Figure 6. Unipolar Input Connections with Gain and Offset Trims

The full-scale trim is done by applying a signal 1 1/2 LSB below the nominal full scale (9.9963 V for a 10 V range) and adjusting R2 until the last transition is located (1111 1111 1110 to 1111 1111 1111). If full-scale adjustment is not required, R2 should be replaced with a fixed 50 Ω ±1% metal film resistor. If REF OUT is connected directly to REF IN, the additional full-scale error will be approximately 1%.

BIPOLAR RANGE INPUTS

The connections for the bipolar-input mode are shown in Figure 7. Either or both of the trimming potentiometers can be replaced with 50 Ω ± 1% fixed resistors if the specified AD1674 accuracy limits are sufficient for the application. If the pins are shorted together, the additional offset and gain errors will be approximately 1%.

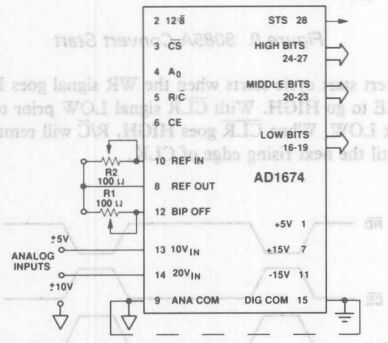

Figure 7. Bipolar Input Connections with Gain and Offset Trims

To trim bipolar offset to its nominal value, apply a signal 1/2 LSB below midrange (−1.22 mV for a ±5 V range) and adjust R1 until the major carry transition is located (0111 1111 1111 to 1000 0000 0000). To trim the full-scale error, apply a signal 1 1/2 LSB below full scale (+4.9963 V for a ±5 V range) and adjust R2 to give the last positive transition (1111 1111 1110 to 1111 1111 1111). These trims are interactive so several iterations may be necessary for convergence.

A single-pass calibration can be done by substituting a negative full-scale trim for the bipolar offset trim (error at midscale), using the same circuit. First, apply a signal 1/2 LSB above minus full scale (−4.9988 V for a ±5 V range) and adjust R1 until the minus full-scale transition is located (0000 0000 0001 to 0000 0000 0000). Then perform the gain error trim as outlined above.

REFERENCE DECOUPLING

It is recommended that a 10 μF tantalum capacitor be connected between REF IN (Pin 10) and ground. This has the effect of improving the S/(N+D) ratio through filtering possible broad-band noise contributions from the voltage reference.

BOARD LAYOUT

Designing with high resolution data converters requires careful attention to board layout. Trace impedance is a significant issue. At the 12-bit level, a 5 mA current through a 0.5 Ω trace will develop a voltage drop of 2.5 mV, which is 1 LSB for a 10 V full-scale range. In addition to ground drops, inductive and capacitive coupling need to be considered, especially when high accuracy analog signals share the same board with digital signals. Finally, power supplies should be decoupled in order to filter out ac noise.

The AD1674 has a wide bandwidth sampling front end. This means that the AD1674 will "see" high frequency noise at the input, which nonsampling (or limited-bandwidth sampling) ADCs would ignore. Therefore, it's important to make an effort to eliminate such high frequency noise through decoupling or by using an anti-aliasing filter at the analog input of the AD1674.

Analog and digital signals should not share a common path. Each signal should have an appropriate analog or digital return routed close to it. Using this approach, signal loops enclose a small area, minimizing the inductive coupling of noise. Wide PC tracks, large gauge wire, and ground planes are highly recommended to provide low impedance signal paths. Separate analog and digital ground planes are also desirable, with a single interconnection point to minimize ground loops. Analog signals should be routed as far as possible from digital signals and should cross them (if necessary) only at right angles.

The AD1674 incorporates several features to help the user's layout. Analog pins are adjacent to help isolate analog from digital signals. Ground currents have been minimized by careful circuit architecture. Current through AGND is 2.2 mA, with little code-dependent variation. The current through DGND is dominated by the return current for DB11–DB0.

SUPPLY DECOUPLING

The AD1674 power supplies should be well filtered, well regulated, and free from high frequency noise. Switching power supplies are not recommended due to their tendency to generate spikes which can induce noise in the analog system.

Decoupling capacitors should be used in very close layout proximity between all power supply pins and ground. A 10 μF tantalum capacitor in parallel with a 0.1 μF disc ceramic capacitor provides adequate decoupling over a wide range of frequencies.

An effort should be made to minimize the trace length between the capacitor leads and the respective converter power supply and common pins. The circuit layout should attempt to locate the AD1674, associated analog input circuitry, and interconnections as far as possible from logic circuitry. A solid analog ground plane around the AD1674 will isolate large switching ground currents. For these reasons, the use of wire-wrap circuit construction is not recommended; careful printed-circuit construction is preferred.

GROUNDING

If a single AD1674 is used with separate analog and digital ground planes, connect the analog ground plane to AGND and the digital ground plane to DGND keeping lead lengths as short as possible. Then connect AGND and DGND together at the AD1674. If multiple AD1674s are used or the AD1674 shares analog supplies with other components, connect the analog and digital returns together once at the power supplies rather than at each chip. This prevents large ground loops which inductively couple noise and allow digital currents to flow through the analog system.

GENERAL MICROPROCESSOR INTERFACE CONSIDERATIONS

A typical A/D converter interface routine involves several operations. First, a write to the ADC address initiates a conversion. The processor must then wait for the conversion cycle to complete, since most ADCs take longer than one instruction cycle to complete a conversion. Valid data can, of course, only be read after the conversion is complete. The AD1674 provides an output signal (STS) which indicates when a conversion is in progress. This signal can be polled by the processor by reading it through

an external three-state buffer (or other input port). The STS signal can also be used to generate an interrupt upon completion of a conversion, if the system timing requirements are critical (bear in mind that the maximum conversion time of the AD1674 is only 10 microseconds) and the processor has other tasks to perform during the ADC conversion cycle. Another possible time-out method is to assume that the ADC will take 10 microseconds to convert, and insert a sufficient number of "no-op" instructions to ensure that 10 microseconds of processor time is consumed.

Once it is established that the conversion is finished, the data can be read. In the case of an ADC of 8-bit resolution (or less), a single data read operation is sufficient. In the case of converters with more data bits than are available on the bus, a choice of data formats is required, and multiple read operations are needed. The AD1674 includes internal logic to permit direct interface to 8-bit or 16-bit data buses, selected by the 12/$\overline{8}$ input. In 16-bit bus applications (12/$\overline{8}$ HIGH) the data lines (DB11 through DB0) may be connected to either the 12 most significant or 12 least significant bits of the data bus. The remaining four bits should be masked in software. The interface to an 8-bit data bus (12/$\overline{8}$ LOW) contains the 8 MSBs (DB11 through DB4). The odd address (A_0 HIGH) contains the 4 LSBs (DB3 through DB0) in the upper half of the byte, followed by four trailing zeroes, thus eliminating bit masking instructions.

	D7						D0
XXX0 (EVEN ADDR):	DB11 (MSB)	DB10	DB9	DB8	DB7	DB6	DB5	DB4
XXX1 (ODD ADDR):	DB3	DB2	DB1	DB0 (LSB)	0	0	0	0

AD1674 Data Format for 8-Bit Bus

8085A INTERFACE

Figure 8 illustrates the use of the AD1674 operating in full-control mode from the 8085A. This provides an example of the implementation of the timing modifications necessary when using the AD1674 in place of an existing AD674A application, discussed in Table II and associated text. Figure 9 shows the convert start timing diagram; Figure 10 provides information on read timing.

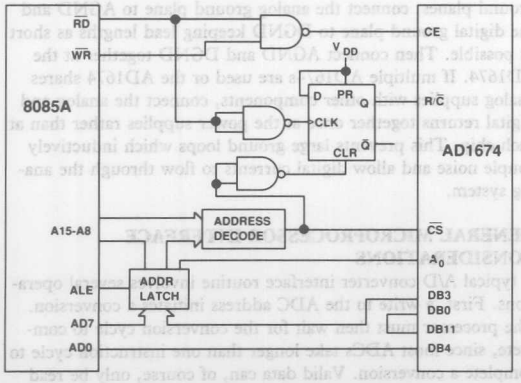

Figure 8. 8085A – AD1674 with R/$\overline{C}$-Delayed Control Interface

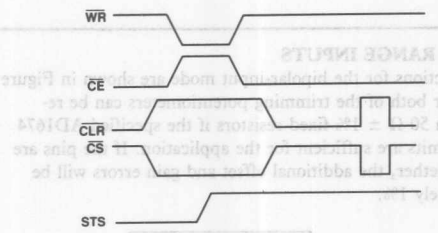

Figure 9. 8085A Convert Start

The convert start cycle starts when the WR signal goes LOW, forcing CE to go HIGH. With $\overline{CLR}$ signal LOW prior to this, R/$\overline{C}$ is set LOW. When $\overline{CLR}$ goes HIGH, R/$\overline{C}$ will remain LOW until the next rising edge of CLK.

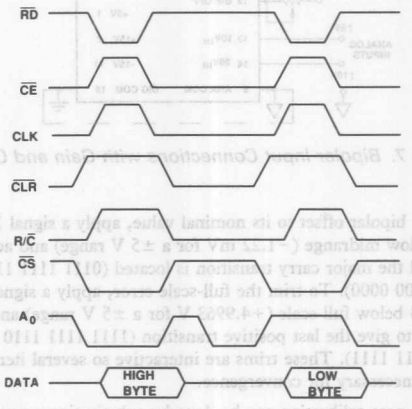

Figure 10. 8085A Read

The High Byte is read first. The Read cycle starts when $\overline{RD}$ goes LOW, causing CE to go HIGH. $\overline{CS}$ is already LOW, making $\overline{CLR}$ and PR HIGH on the D-flop. This causes R/$\overline{C}$ to go HIGH on the rising edge of CLK. R/$\overline{C}$ will not go LOW until $\overline{CS}$ goes HIGH, forcing $\overline{CLR}$ to go LOW thus putting the D-flop in a steady state of Q LOW. The cycle repeats for the Low Byte read.

FUNCTIONAL BLOCK DIAGRAM

PRODUCTION DESCRIPTION

The AD1876 is a 16-bit serial output sampling A/D converter which uses a switched capacitor/charge redistribution architecture to achieve a 100 kSPS conversion rate (10 μs total conversion time). Overall performance is optimized by digitally correcting internal nonlinearities through on-chip autocalibration.

The circuitry of the AD1876 is partitioned onto two monolithic chips, a digital control chip fabricated with Analog Devices' DSP CMOS process and an analog ADC chip fabricated with the BiMOS II process. Both chips are contained in a single package.

The serial output interface requires an external clock and sample command signal. The output data rate may be as high as 2.08 MHz, and is controlled by the external clock. The twos complement format of the output data is MSB first and is directly compatible with the NPC SM5805 digital decimation filter used in consumer audio products. The AD1876 is also compatible with a variety of DSP processors.

The AD1876 is packaged in a space saving 16-pin plastic DIP and operates from +5 V and ±12 V supplies; typical power consumption is 235 mW. The digital supply (V_{DD}) is isolated from the linear supplies (V_{EE} and V_{CC}) for reduced digital crosstalk. Separate analog and digital grounds are also provided.

AD1876—SPECIFICATIONS (T_{min} to T_{max}, V_{CC} = +12 V ± 5%, V_{EE} = −12 V ± 5%, V_{DD} = +5 V ± 10%)[1]

ABSOLUTE MAXIMUM RATINGS*

V_{CC} to V_{EE} . . . . . −0.3 V to +26.4 V
V_{DD} to DGND . . . . . −0.3 V to +7 V
V_{CC} to AGND . . . . . −0.3 V to +18 V
V_{EE} to AGND . . . . . −18 V to +0.3 V
AGND to DGND . . . . . ±0.3 V
Digital Inputs to DGND . . . . . 0 V to 5.5 V
Analog Inputs, V_{REF} to AGND . . . . . (V_{CC} + 0.3 V) to (V_{EE} −0.3 V)
Soldering . . . . . +300°C, 10 sec
Storage Temperature . . . . . −60°C to +100°C

*Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD SENSITIVITY

The AD1876 features input protection circuitry consisting of large "distributed" diodes and polysilicon series resistors to dissipate both high energy discharges (Human Body Model) and fast, low energy pulses (Charged Device Model). Per Method 3015.2 of MIL-STD-883C, the AD1876 has been classified as a Category 1 Device.

Proper ESD precautions are strongly recommended to avoid functional damage or performance degradation. Charges as high as 4000 volts readily accumulate on the human body and test equipment, and discharge without detection. Unused devices must be stored in conductive foam or shunts, and the foam discharged to the destination socket before devices are removed. For further information on ESD precaution, refer to Analog Devices' *ESD Prevention Manual.*

TIMING SPECIFICATIONS[1] (T_{min} to T_{max}, V_{CC} = +12 V ± 5%, V_{EE} = −12 V ± 5%, V_{DD} = +5 V ± 10%, V_{REF} = 5.00 V)

Parameter	Symbol	Min	Typ	Max	Units
Sampling Rate[2]	$f_S = 1/t_S$	1		100	kSPS
Sampling Period[2]	$t_S = 1/f_S$	10		1000	μs
Acquisition Time (Included in t_S)	t_A	2			μs
Calibration Time	t_{CT}			5000	t_C

SAMPLE LOW	t_{SL}	50			ns

NOTES
[1]See Figure 1 and Figure 2 and the Conversion Control and Autocalibration sections for detailed explanations of the above timing.
[2]Depends upon external clock frequency; includes acquisition time and conversion time. The minimum sampling rate/maximum sampling period is specified to account for droop of the internal sample/hold. Operation at slower rates than specified may degrade performance.

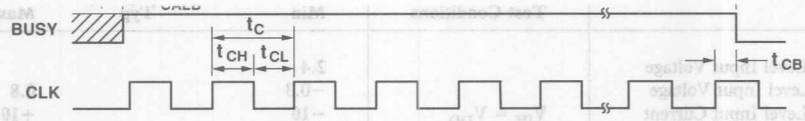

Figure 1. AD1876 Calibration Timing

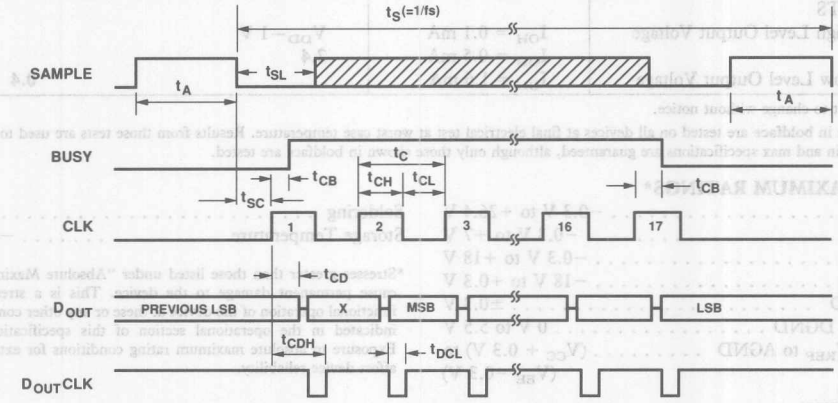

Figure 2. Recommended AD1876 Conversion Timing

Definition of Specifications

NYQUIST FREQUENCY

An implication of the Nyquist sampling theorem, the "Nyquist Frequency" of a converter is that input frequency which is one-half the sampling frequency of the converter.

TOTAL HARMONIC DISTORTION

Total harmonic distortion (THD) is measured as the ratio of the rms sum of the first nineteen harmonic components to the rms value of a 1 kHz full-scale sine wave input signal and is expressed in percent (%) or decibels (dB). For input signals or harmonics that are above the Nyquist frequency, the aliased component is used.

SIGNAL-TO-NOISE PLUS DISTORTION RATIO

Signal-to-noise plus distortion (S/N+D) is defined to be the ratio of the rms value of the measured input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc.

D-RANGE DISTORTION

D-range distortion is the ratio of the distortion plus noise to the signal at a signal amplitude of −60 dB. In this case, an A-weight filter is used. The value specified for D-range performance is the ratio measured plus 60 dB.

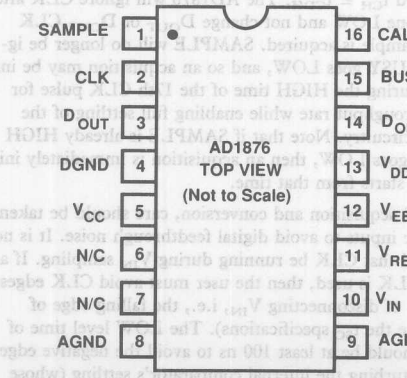
BANDWIDTH

The full power bandwidth is that input frequency at which the amplitude of the reconstructed fundamental is reduced by 3 dB for a full-scale input.

INTERMODULATION DISTORTION (IMD)

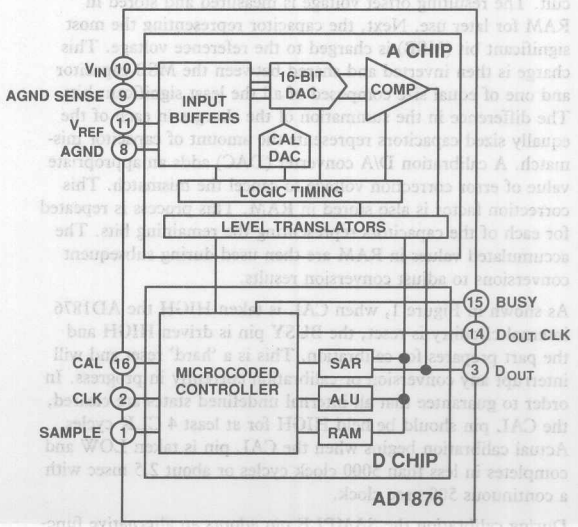
With inputs consisting of sine waves at two frequencies, f_a and f_b, any device with nonlinearities will create distortion products, of order (m+n), at sum and difference frequencies of $mf_a \pm nf_b$, where m, n = 0, 1, 2, 3 . . . . Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms are $(f_a + f_b)$ and $(f_a - f_b)$, and the third order terms are $(2f_a + f_b)$, $(2f_a - f_b)$, $(f_a + 2f_b)$ and $(f_a - 2f_b)$. The IMD products are expressed as the decibel ratio of the rms sum of the measured input signals to the rms sum of the distortion terms. The two signals applied to the converter are of equal amplitude, and the peak value of their sum is −0.05 dB from full scale. The IMD products are normalized to a 0 dB input signal.

APERTURE DELAY



Aperture delay is the time required after SAMPLE is taken LOW for the internal sample-hold of the AD1876 to open, thus holding the value of V_{IN}.

APERTURE JITTER



Aperature jitter is the variation in the aperture delay from sample to sample.

Pin No.	Name	Type	Description
1	SAMPLE	DI	V_{IN} Acquisition Control Pin. During conversion, SAMPLE controls the state of the internal Sample-Hold Amplifier and initiates conversion (see "Conversion Control" paragraph). During calibration, SAMPLE is active HIGH, forcing D_{OUT} (Pin 3) LOW. If SAMPLE is LOW during calibration, D_{OUT} will output diagnostic information (See "Autocalibration" paragraph.)
2	CLK	DI	Master Clock Input. The AD1876 requires 17 clock pulses to execute a conversion. CLK is also used to derive D_{OUT} CLK (Pin 14). During calibration, 5000 clock pulses are applied.
3	D_{OUT}	DO	Serial Output Data, Twos Complement format.
4	DGND	P	Digital Ground.
5	V_{CC}	P	+12 V Analog Supply Voltage.
6	N/C	–	No Connection.
7	N/C	–	No Connection.
8	AGND	P/AI	Analog Ground.
9	AGND SENSE	AI	Analog Ground Sense.
10	V_{IN}	AI	Analog Input Voltage, referred the AGND SENSE.
11	V_{REF}	AI	External Voltage Reference Input, referred to AGND.
12	V_{EE}	P	−12 V Analog Supply Voltage.
13	V_{DD}	P	+5 V Logic Supply Voltage.
14	D_{OUT} CLK	DO	The rising edge of D_{OUT} CLK may be used to latch D_{OUT} (Pin 3). D_{OUT} CLK is derived from CLK.
15	BUSY	DO	Status Line for Converter. Active HIGH, indicating a conversion or calibration in progress.
16	CAL	DI	Calibration Control Pin (asynchronous).

Type: AI = Analog Input.
DI = Digital Input.
DO = Digital Output.
P = Power.

Package Pinout

Functional Block Diagram

FUNCTIONAL DESCRIPTION

The AD1876 is a 16-bit analog-to-digital converter including a sample/hold input circuit, successive approximation register, ground sensing circuitry, serial output port and a microcontroller based autocalibration circuit. These functions are segmented onto two monolithic chips, an analog signal processor and a digital controller. Both chips are contained within the AD1876 package.

The AD1876 employs a successive-approximation technique to determine the value of the analog input voltage. However, instead of the traditional laser-trimmed resistor-ladder approach, the AD1876 uses a capacitor-array, charge-redistribution technique. An array of binary-weighted capacitors subdivides the input value to perform the actual analog to digital conversion. This capacitor array also serves a sample/hold function without the need for additional external circuitry.

The autocalibration circuit within the AD1876 employs a microcontroller and calibration DAC to measure and compensate capacitor mismatch errors. As each error is determined, its value is stored in on-chip memory (RAM). Subsequent conversions use these RAM values to improve conversion accuracy. The autocalibration routine may be invoked at any time. Autocalibration insures high performance while eliminating the need for any user adjustments, and is described in detail below.

The microcontroller controls all of the various functions within the AD1876. These include the actual successive approximation routine, the autocalibration routine, the sample/hold operation, and the serial data transmission.

AUTOCALIBRATION

The AD1876 achieves rated performance without the need for user trims or adjustments. This is accomplished through the use of on-chip autocalibration.

In the autocalibration sequence, sample/hold offset is nulled by internally connecting the input circuit to the ground sense circuit. The resulting offset voltage is measured and stored in RAM for later use. Next, the capacitor representing the most significant bit (MSB) is charged to the reference voltage. This charge is then inverted and shared between the MSB capacitor and one of equal size composed of all the least significant bits. The difference in the summation of the charges in each of the equally sized capacitors represents the amount of capacitor mismatch. A calibration D/A converter (DAC) adds an appropriate value of error correction voltage to cancel the mismatch. This correction factor is also stored in RAM. This process is repeated for each of the capacitors representing the remaining bits. The accumulated values in RAM are then used during subsequent conversions to adjust conversion results.

As shown in Figure 1, when CAL is taken HIGH the AD1876 internal circuitry is reset, the BUSY pin is driven HIGH and the part prepares for calibration. This is a 'hard' reset and will interrupt any conversion or calibration currently in progress. In order to guarantee that all internal undefined states are cleared, the CAL pin should be held HIGH for at least 4 CLK cycles. Actual calibration begins when the CAL pin is taken LOW and completes in less than 5000 clock cycles or about 2.5 msec with a continuous 500 nsec clock.

During calibration the SAMPLE pin adopts an alternative function. If it is held LOW, D_{OUT} provides diagnostic test information (not intended to be used by the customer). If SAMPLE is held HIGH, D_{OUT} will be forced LOW. In either case, D_{OUT} CLK will continue pulsing. Since the SAMPLE pin has no control over the actual calibration process, normal conversion timing may also be used for calibration. In this case, however, the D_{OUT} pin will output test information during those periods that SAMPLE is LOW. BUSY going LOW will always indicate the end of calibration.

A calibration sequence should be followed by one "dummy" conversion to clear the internal circuitry of the AD1876 in order to guarantee subsequent conversion accuracy.

In most applications, it is sufficient to calibrate the AD1876 only upon power-up, in which case care should be taken that the power supplies and voltage reference have stabilized first.

CONVERSION CONTROL

The AD1876 is controlled by two signals: SAMPLE and CLK, as shown in Figure 2. It is assumed that the part has been calibrated and the digital I/O pins have the levels shown at the start of the timing diagram.

A conversion consists of an input acquisition followed by 17 clock pulses which are required to run the 16-bit internal successive approximation routine. The analog input is acquired by taking the SAMPLE line HIGH for a minimum acquisition time of t_A. The actual sample taken is the voltage present on V_{IN} at the instant the SAMPLE pin is brought LOW. Care should be taken to ensure that this negative edge is well defined and jitter free to reduce the uncertainty (noise) in ac signal acquisition. On that edge the AD1876 commits itself to the initiated conversion—the input at V_{IN} is disconnected from the internal capacitor array and the SAMPLE input will be ignored until the conversion is completed (i.e., BUSY goes LOW). After a delay of at least t_{SC} (SAMPLE to CLK setup) the 17 CLK cycles are applied. BUSY is asserted after the first positive edge on CLK and reset after the 17th. Both the D_{OUT} and the D_{OUT} CLK outputs are generated in response to the rising edges of valid CLK pulses. As indicated in the timing diagram, the 2s complement output data is presented MSB first. This data may be captured with the rising edge of D_{OUT} CLK or the falling edge of CLK provided $t_{CH} \geq t_{CDH}$. The AD1876 will ignore CLK after BUSY has gone LOW and not change D_{OUT} or D_{OUT} CLK until a new sample is acquired. SAMPLE will no longer be ignored after BUSY goes LOW, and so an acquisition may be initiated even during the HIGH time of the 17th CLK pulse for maximum throughput rate while enabling full settling of the sample/hold circuitry. Note that if SAMPLE is already HIGH when BUSY goes LOW, then an acquisition is immediately initiated and t_A starts from that time.

During signal acquisition and conversion, care should be taken with the logic inputs to avoid digital feedthrough noise. It is not recommended that CLK be running during V_{IN} sampling. If a continuous CLK is used, then the user must avoid CLK edges at the instant of disconnecting V_{IN}, i.e., the falling edge of SAMPLE (see the t_{SC} specifications). The LOW level time of CLK (t_{CL}) should be at least 100 ns to avoid the negative edge transition disturbing the internal comparator's settling (whose decision is latched on the positive edge of each valid CLK). For the same reason, it is also not recommended that the SAMPLE pin change state during conversion (i.e., until after BUSY returns LOW).

Internal dc error terms such as comparator voltage offset are sampled, stored on internal capacitors and used to correct for their corresponding errors when needed. Because these voltages

are stored on capacitors, they are subject to leakage decay and so require refreshing. For this reason the part is required to be run continuously—i.e., there is a minimum t_S specification. If the part has been idle for too long (i.e., t_S has expired) then a dummy conversion cycle is required to refresh these correction voltages.

BUSY is HIGH during a conversion and goes LOW when the conversion is completed. The twos complement output data is presented MSB first, with MSB data valid on the rising edge of the second D_{OUT} CLK pulse. Subsequent data is valid on rising edges of subsequent D_{OUT} CLK pulses. Table I illustrates the AD1876 output coding.

V_{IN}	Output Code
−Full Scale	100. . . 00
−Full Scale + 1 LSB	100. . . 01
Midscale − 1 LSB	111. . . 11
Midscale	000. . . 00
Midscale + 1 LSB	000. . . .01
Full Scale − 1 LSB	011. . . 10
Full Scale	011. . . 11

Table I. Serial Output Coding Format (Twos Complement)

A simple method for generating the required signals for the AD1876 is to connect one or more AD1876s to an NPC SM5805 digital filter. This device supplies all signals required to operate the AD1876 at a 96 kHz sample rate, which is 2 × F_S for audio applications. This is more fully discussed in the applications section of this data sheet, accompanied by Figures 9 and 10.

APPLICATIONS

POWER SUPPLIES AND DECOUPLING

The AD1876 has three power supply input pins. V_{EE} and V_{CC} provide the supply voltages to operate the analog portions of the AD1876 including the ADC and SHA. V_{DD} provides the supply voltage which operates the digital portions of the AD1876 including the serial output port and the autocalibration controller.

Decoupling capacitors should be used on all power supply pins. These capacitors should be placed as close as possible to the package pins as well as the ground connections. The logic supply (V_{DD}) should be decoupled to digital common (DGND) with a 0.1 μF ceramic capacitor, and the analog supplies (V_{EE} and V_{CC}) should be decoupled to analog common (AGND) with 4.7 μF and 0.1 μF tantalum capacitors in parallel, represented by C1. An effort should be made to minimize the trace length between the capacitor leads and the respective converter power supply and common pins. The recommended decoupling scheme is illustrated in Figure 3.

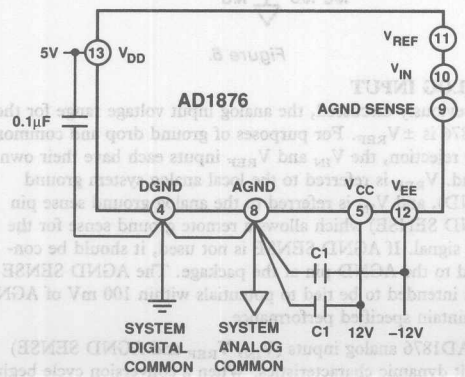


Figure 3. Grounding and Decoupling the AD1876

As with most high performance linear circuits, changes in the power supplies can produce undesired changes in the performance of the circuit. Analog Devices recommends that well regulated power supplies with less than 1% ripple be incorporated into the design of any system using these devices.

BOARD LAYOUT

Designing with high resolution data converters requires careful attention to board layout. Trace impedance is a significant issue. A 1.22 mA current through a 0.5 Ω trace will develop a voltage drop of 0.6 mV, which is 4 LSBs at the 16 bit level for a 10 V full-scale span. In addition to ground drops, inductive and capacitive coupling need to be considered, especially when high accuracy analog signals share the same board with digital signals. Finally, power supplies need to be decoupled in order to filter ac noise.

Analog and digital signals should not share a common return path. Each signal should have an appropriate analog or digital return routed close to it. Using this approach, signal loops enclose a small area, minimizing the inductive coupling of noise. Wide PC tracks, large gauge wire, and ground planes are highly recommended to provide low impedance signal paths. Separate analog and digital ground planes are also desirable, with a single interconnection point to minimize ground loops. Analog signals should be routed as far as possible from digital signals and should cross them, if at all, only at right angles. A solid analog ground plane around the AD1876 will isolate large switching ground currents. For these reasons, the use of wire wrap circuit construction is not recommended; careful printed circuit construction is preferred.

GROUNDING

The AD1876 has three grounding pins, designated ANALOG GROUND (AGND), DIGITAL GROUND (DGND) and ANALOG GROUND SENSE (AGND SENSE). The analog ground pin is the "high quality" ground reference point for the device. The analog ground pin should be connected to the analog common point in the system.

AGND SENSE is intended to be connected to the input signal ground reference point. This allows for slight differences in level between the analog ground point in the system and the input signal ground point. However, no more than 100 mV is recommended between the analog ground pin and the analog ground sense pin for specified performance.

The digital ground pin is the reference point for all of the digital signals that operate the AD1876. This pin should be connected to the digital common point in the system. As illustrated in Figure 3, the analog and digital grounds should be connected together at one point in the system.

The input voltage range is determined by the value of the reference voltage; in general, a reference voltage of n volts produces an input range of ±n volts. Signal-to-noise performance is increased proportionately with input signal range. The AD1876 is specified with a 5.0 V reference and an analog input of ±5 V. In the presence of a fixed amount of system noise, increasing the LSB size (which results from increasing the reference voltage) will increase the effective S/(N+D) performance for input values below the point where input distortion occurs. Figure 11 illustrates S/(N+D) as a function of input amplitude and reference voltage.

During a conversion, the switched capacitor array of the AD1876 presents a dynamically changing current load at the voltage reference as the successive-approximation algorithm cycles through various choices of capacitor weighting. The output impedance of the reference circuitry must be low so that the output voltage will remain sufficiently constant as the current drive changes. In most applications, this requires that the output of the voltage reference be buffered by an amplifier with low impedance at relatively high frequencies. A (10 μF or larger) capacitor connected between V_{REF} and AGND will reduce the demands on the reference by decreasing the magnitude of high frequency components.

The following two sections represent typical design approaches.

VOLTAGE REFERENCE—AUDIO APPLICATIONS

Audio applications require optimal ac performance over a relatively narrow temperature range, with low cost being important. Figure 4 shows one such approach towards attaining these goals. A voltage reference, consisting of a Zener diode, capacitor, resistor and op amp with typical component values, is shown. This simple circuit has the advantage of low cost, but the reference voltage value is sensitive to changes in the +12 V supply. Additionally, changes in the Zener value due to temperature variations will also be reflected in the reference voltage. R_{OPTION} may be required for other component selections if the Zener requires more current than the op amp can supply.

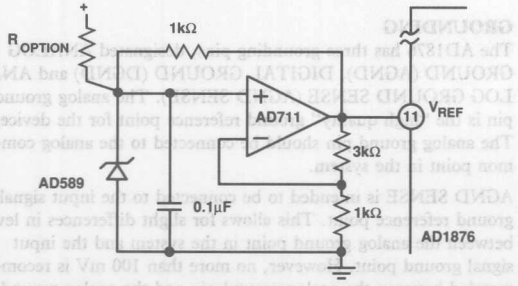

Figure 4. Low Cost Voltage Reference Circuit

VOLTAGE REFERENCE—PRECISION MEASUREMENT APPLICATIONS

In applications other than audio, parameters such as low drift over temperature and static accuracy are important. Figure 5 shows a voltage reference circuit featuring the 5 V AD586. The AD586 is a low cost reference which utilizes a buried Zener architecture to provide low noise and drift. Over the 0°C to +70°C tor, C_N, reduces the broadband noise of the AD586 output, thereby optimizing the overall performance of the AD1876.

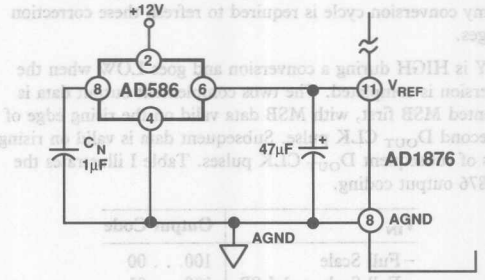

Figure 5.

For higher performance needs, the AD588 reference provides improved drift, low noise, and excellent initial accuracy. The AD588 uses a proprietary ion-implanted buried Zener diode in conjunction with laser-trimmed thin-film resistors for low offset and gain. The AD588 output is accurate to 0.65 mV from its value at +25°C over the 0°C to +70°C range. The circuit shown in Figure 6 includes a noise-reduction network on Pins 4, 6 and 7. The 1 μF capacitors form low pass filters with the internal resistance of the AD588 and external 3.9 kΩ resistor. This reduces the wide-band (to 1 MHz) noise of the AD588, providing optimum performance of the AD1876.

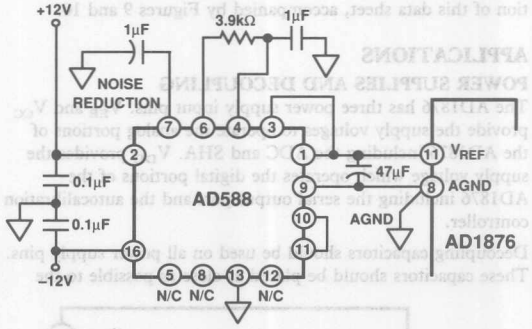

Figure 6.

ANALOG INPUT

As previously discussed, the analog input voltage range for the AD1876 is $\pm V_{REF}$. For purposes of ground drop and common-mode rejection, the V_{IN} and V_{REF} inputs each have their own ground. V_{REF} is referred to the local analog system ground (AGND), and V_{IN} is referred to the analog ground sense pin (AGND SENSE) which allows a remote ground sense for the input signal. If AGND SENSE is not used, it should be connected to the AGND pin at the package. The AGND SENSE pin is intended to be tied to potentials within 100 mV of AGND to maintain specified performance.

The AD1876 analog inputs (V_{IN}, V_{REF} and AGND SENSE) exhibit dynamic characteristics. When a conversion cycle begins, each analog input is connected to an internal, discharged 50 pF capacitor which then charges to the voltage present at the corresponding pin. The capacitor is disconnected when SAMPLE is

external source by this high initial charging current, an internal buffer amplifier is employed between the input and this capacitance for a few hundred nanoseconds. During this time the input pin exhibits typically 20 kΩ input resistance, 10 pF input capacitance and ±40 μA bias current. Next, the input is switched directly to the now precharged capacitor and allowed to fully settle, after which SAMPLE is taken LOW. During this time the input sees only a 50 pF capacitor. Once the sample is taken, the input is internally floated so that the external input source sees a very high input resistance and a parasitic input capacitance of typically only 2 pF. As a result, the only dominant input characteristic which must be considered is the high current steps which occur when the internal buffers are switched in and out.

In most cases, it is desirable to use external op amps to drive the AD1876. For ac applications where low cost and low distortion are desired, the AD711 may be used as shown in Figure 7. Another option is the 5532/5534 series. Care should always be taken with op amp selection—many available op amps do not meet the necessary low distortion requirements with even moderate loading conditions.

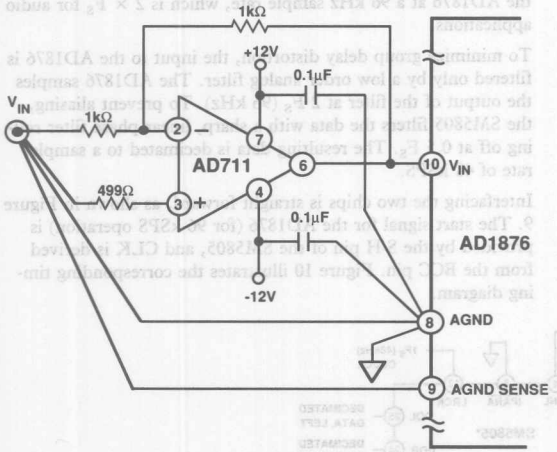

Figure 7.

TESTING THE AD1876

Analog Devices employs a high performance mixed signal VLSI tester to verify the electrical performance of every AD1876. The test system consists of two main sections, an input signal generator and a digital data and control section.

The stimulus section is responsible for providing a high purity, noise-free, band limited tone to the input of the device. This input frequency is 1.06 kHz. The test tone is passed through a bandpass filter to remove distortion products and then buffered by a high performance op amp. An external 5.000 V reference voltage is also supplied by this section.

The control section of the test equipment provides an external clock and the control signals for calibration, conversion and data transmission. This section of the tester also contains the processing unit that calculates the actual performance of the device under test.

under test digitizes the input waveform. This conversion is performed at a 96 kSPS rate and transmits the resulting serial data to the tester. The tester performs an FFT on the test data and determines the actual performance of the device.

AC PERFORMANCE

Using the aforementioned test methodology, ac performance of the AD1876 is measured. AC parameters, which include S/(N+D), THD, etc., reflect the AD1876's effect on the spectral content of the analog input signal. Figures 11 through 15 provide information on the AD1876's ac performance under a variety of conditions.

As a general rule, averaging the results from several conversions reduces the effects of noise and, therefore, improves such parameters as S/(N+D) and THD. AD1876 performance is optimized by operating the device at its maximum sample rate of 100 kSPS and digitally filtering the resulting bit stream to the desired signal bandwidth. This succeeds in distributing noise over a wider frequency range, thus reducing the noise density in the frequency band of interest. This subject is discussed in the following section.

OVERSAMPLING AND NOISE FILTERING

The Nyquist rate for a converter is defined as one-half its sampling rate. This is established by the Nyquist theorem, which requires that a signal be sampled at a rate corresponding to at least twice its widest bandwidth of interest in order to preserve the information content. Oversampling is a conversion technique in which the sampling frequency is an integral (2 or more) multiple of twice the frequency bandwidth of interest. In audio applications, the AD1876 can operate at a 2× oversampling rate.

In quantized systems, the information content of the analog input is represented in the frequency spectrum from dc to the Nyquist rate of the converter. Within this same spectrum are higher frequency aliased noise components. Antialias, or lowpass, filters are used at the input to the ADC to remove the portion of these noise components attributed to high frequency analog input noise. However, wideband noise contributed by the AD1876 will not be reduced by the antialias filter. The AD1876 contributed noise is evenly distributed from dc to the Nyquist rate, and this fact can be used to minimize its overall effect.

The AD1876 contributed noise effects can be reduced by oversampling—sampling at a rate higher than defined by the Nyquist theorem. This spreads the noise energy over a distribution of frequencies wider than the frequency band of interest, and by judicious selection of a digital filter, noise frequencies outside the bandwidth of interest may be eliminated. The process of quantization inherently produces noise, known as quantization noise. The magnitude of this noise is a function of the resolution of the converter, and manifests itself as a limit to the theoretical signal-to-noise ratio achievable. This limit is described by $S/(N+D) = (6.02\ n + 1.76 + 10 \log F_S/2\ F_a)$ dB, where n is the resolution of the converter in bits, F_S is the sampling frequency, and F_a is the signal bandwidth of interest. For audio bandwidth applications, the AD1876 is capable of operating at a 2× oversample rate (96 kSPS), which typically produces an improvement in S/(N+D) of 3 dB compared with operating at the Nyquist conversion rate of 48 kSPS. Oversampling has another advantage as well; the demands on the antialias filter are

lessened. In summary, system performance is optimized by running the AD1876 at or near its maximum sampling rate of 100 kHz and digitally filtering the resulting spectrum to eliminate undesired frequencies.

DSP INTERFACE

Figure 8 illustrates the use of the Analog Devices ADSP-2101 digital signal processor with the AD1876. The ADSP-2101 FO (flag out) pin of serial port 1 (SPORT 1) is connected to the SAMPLE line and is used to control acquisition of data. The ADSP-2101 timer is used to provide precise timing of the FO pin.

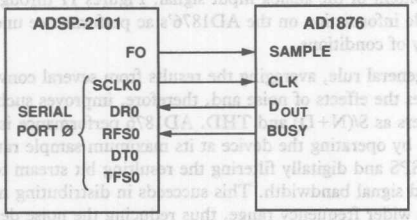

Figure 8. ADSP-2101 Interface

The SCLK pin of the ADSP-2101 SPORT0 provides the CLK input for the AD1876. The clock should be programmed to be approximately 2 MHz to comply with AD1876 specifications. To minimize digital feedthrough, the clock should be disabled (by setting Bit 14 in SPORT0 control register to 0) during data acquisition. Since the clock floats when disabled, a pulldown resistor of 12 k–15 kΩ should be connected to SCLK to ensure it will be LOW at the falling edge of SAMPLE. To maximize the conversion rate, the serial clock should be enabled immediately after SAMPLE is brought LOW (hold mode).

The AD1876 BUSY signal is connected to RF0 to notify SPORT0 when a new data word is coming. SPORT0 should be configured in normal, external, noninverting framing mode and can be programmed to generate an interrupt after the last data bit is received. To maximize the conversion rate, SAMPLE should be brought HIGH immediately after the last data bit is received.

SIGNAL PROCESSING

An audio spectrum analyzer can be produced by combining an AD1876 and an ADSP-2101 signal processing microcomputer. This system can analyze signals from dc to 50 kHz depending on the sample rate. This is ideal for applications such as audio analysis, but could also be applied to vibration analysis as well.

AUDIO DELAY LINE

A high performance, 16-bit stereo delay line can be constructed from two AD1876 audio ADCs, a signal processing microcomputer and two AD1856 audio DACs. Depending on the length of the internal buffer which produces the delay, a variable delay is possible. Other applications are also possible with only a change in software. For example, a reverb or echo effect could be generated as well.

AD1876 AND SM5805 DIGITAL FILTER @ 2 F_S

A simple method for generating the required signals for the AD1876 is to connect one or more AD1876s to an NPC SM5805 digital filter. This device supplies all signals required to operate the AD1876 at a 96 kHz sample rate, which is 2 × F_S for audio applications.

To minimize group delay distortion, the input to the AD1876 is filtered only by a low order analog filter. The AD1876 samples the output of the filter at 2 F_S (96 kHz). To prevent aliasing, the SM5805 filters the data with a sharp, linear phase filter rolling off at 0.5 F_S. The resulting data is decimated to a sample rate of 48 kSPS.

Interfacing the two chips is straight forward, as shown in Figure 9. The start signal for the AD1876 (for 96 kSPS operation) is provided by the S/H pin of the SM5805, and CLK is derived from the BCC pin. Figure 10 illustrates the corresponding timing diagram.

16-Bit Oversampled ADC

AD1878

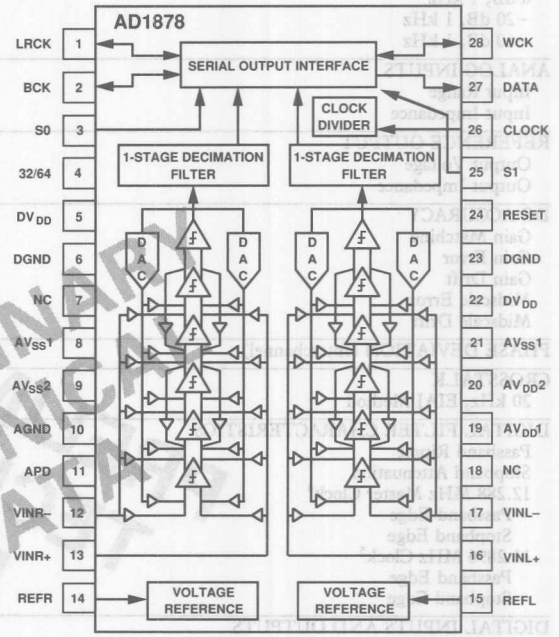
FEATURES

- Dual Channel
- 98 dB Signal-to-Noise Ratio
- 98 dB THD+N
- 0.0004 dB Passband Ripple
- 115 dB Stopband Attenuation
- 64× Oversampling
- Linear Phase

APPLICATIONS

- DAT and DCC Tape Players
- Direct-to-Disc Recorders
- Digital Audio Editors
- Digital Mixing Consoles

PRODUCT DESCRIPTION



The AD1878 is a two-channel, 16-bit oversampled digital audio ADC. Each channel incorporates a high performance one-bit noise shaping modulator and a digital decimating filter. An on-board voltage reference is also included. ADC output data is transmitted from a flexible serial data port. The circuitry of the AD1878 is segmented between two monolithic chips.

The voltage reference and one-bit modulators are fabricated on a BiCMOS chip. The reference circuitry provides a reference voltage that is stable over temperature and time. Using an external master clock, the one-bit modulators operate at a 64 × F_S oversampling ratio. This oversampling ratio permits the antialias filters to be simple resistor-capacitor combinations and results in linear phase throughout the passband. The modulators are 5th order and employ differential switched capacitor filters to provide the required noise shaping characteristics and extremely low distortion.

The digital decimating filters and serial port are fabricated using a CMOS process. Using a proprietary technique, these single-stage digital filters provide a narrow transition band, deep stopband attenuation and low passband ripple.

The output port provides a single, serial bit stream which can operate in several MASTER or SLAVE modes. It is controlled by a clock and mode select pins. The format of the data is twos complement, MSB first. The output signals are TTL and 5 volt CMOS compatible. Output words may be transmitted in a right-justified, I^2S or user-defined format.

FUNCTIONAL BLOCK DIAGRAM

The AD1878 operates with ±5 volt power supplies. Separate digital and analog power supplies and ground connections are provided for reduced digital crosstalk. The AD1878 is guaranteed to operate over a temperature range of −25°C to +70°C and is packaged in a 28-pin plastic DIP.

PRODUCT HIGHLIGHTS

1. 64 × F_S sampling rate.
2. From 2.5 kHz to 50 kHz output word rates.
3. Passband ripple is less than 0.001 dB.
4. Stopband attenuation is 115 dB.
5. Excellent low level signal performance is achieved.
6. No sample-and-hold circuits are required.

LC²MOS Complete, High Speed 12-Bit ADC

AD7572

FEATURES

- 12-Bit Resolution and Accuracy
- Fast Conversion Time
  - AD7572XX05: 5μs
  - AD7572XX12: 12.5μs
- Complete with On-Chip Reference
- Fast Bus Access Time: 90ns
- Low Power: 135mW
- Small, 0.3", 24-Pin Package and 28-Terminal Surface Mount Packages

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7572 is a complete, 12-bit ADC that offers high speed performance combined with low, CMOS power levels. The AD7572 uses an accurate, high speed DAC and comparator in a successive-approximation loop to achieve a fast conversion time. An on-chip, buried Zener diode provides a stable reference voltage to give low drift performance over the full temperature range and the specified accuracy is achieved without any user trims. An on-chip clock circuit is provided, which may be used with a crystal for stand-alone operation, or the clock input may be driven from an external clock source such as a divided-down microprocessor clock. The only other external components required for basic operation of the AD7572 are decoupling capacitors for the supply voltages and reference output.

The AD7572 has a high speed digital interface with three-state data outputs and can operate under the control of standard microprocessor Read ($\overline{RD}$) and decoded address ($\overline{CS}$) signals. Interface timing is sufficiently fast to allow the AD7572 to operate with most popular microprocessors, with three-state enable times of only 90ns and bus relinquish times of 75ns.

The AD7572 is fabricated in Analog Devices Linear Compatible CMOS process (LC²MOS), an advanced, all ion-implanted process that combines fast CMOS logic and linear, bipolar circuits on a single chip, thus achieving excellent linear performance while still retaining low CMOS power levels.

The AD7572 is available in both 0.3" wide , 24-pin DIPs and in a 28-terminal plastic leaded chip carrier (PLCC) and leadless ceramic chip carrier (LCCC).

PRODUCT HIGHLIGHTS

1. Fast, 5μs and 12.5μs conversion times make the AD7572 ideal for a wide range of applications in telecommunications, sonar and radar signal processing or any wideband data acquisition system.
2. On-chip buried-Zener reference has temperature coefficient as low as 25ppm/°C, giving low full-scale drift over the operating temperature range.
3. Stable DAC and comparator give excellent linearity and low zero error over the full temperature range.
4. Fast, easy-to-use digital interface has three-state bus access times of 90ns and bus relinquish times of 75ns, allowing the AD7572 to interface to most popular microprocessors.
5. LC²MOS circuitry gives low power drain (135mW) from +5, −15 volt supplies.
6. 24-pin 0.3" package offers space saving over parts in 28-pin 0.6" DIP.

NOTES
[1]Timing Specifications are sample tested at +25°C to ensure compliance. All input control signals are specified with tr = tf = 5ns (10% to 90% of +5V) and timed from a voltage level of 1.6V.
[2]t_3 and t_6 are measured with the load circuits of Figure 1 and defined as the time required for an output to cross 0.8V or 2.4V.
[3]t_7 is defined as the time required for the data lines to change 0.5V when loaded with the circuits of Figure 2.
Specifications subject to change without notice.

*Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other condition above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

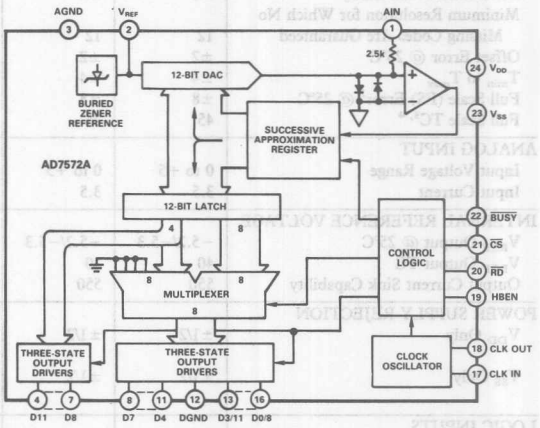
LC²MOS Complete, High Speed 12-Bit ADC

AD7572A

FEATURES



Improved AD7572
- **Faster Conversion Time**
  - **AD7572AXX03: 3 μs**
  - **AD7572AXX10: 10 μs**
- **5 V and −12 V or −15 V Power Supply Operation**
- **Better Offset and Gain Error Specifications**

Extended Plastic Temperature Range (−40°C to +85°C)

Low Power: 100 mW

Small 24-Pin, 0.3″ Wide DIP and SOIC DIP Packages

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7572A is an enhanced replacement for the industry standard AD7572. Improvements include faster conversion times of 3 μs for the AD7572AXX03 and 10 μs for the AD7572AXX10. The required power supplies are 5 V and −12 V or −15 V. Additional features are better offset and gain error specifications over the original AD7572.

The AD7572A is a complete 12-bit ADC that offers high speed performance combined with low, CMOS power levels. The part uses an accurate, high speed DAC and comparator in a successive-approximation loop to achieve a fast conversion time. An on-chip buried Zener diode provides a stable reference voltage to give low drift performance over the full temperature range and the specified accuracy is achieved without any user trims. An on-chip clock circuit is provided, which may be used with a crystal for stand-alone operation, or the clock input may be driven from an external clock source such as a divided-down microprocessor clock. The only other external components required for basic operation of the AD7572A are decoupling capacitors for the supply voltages and reference output.

The AD7572A has a high speed digital interface with three-state data outputs and can operate under the control of standard microprocessor Read ($\overline{RD}$) and decoded address ($\overline{CS}$) signals. Interface timing is sufficiently fast to allow the AD7572A to operate with most microprocessors, with three-state enable times of only 90 ns and bus relinquish times of 75 ns.

The AD7572A is fabricated in Analog Devices Linear Compatible CMOS process (LC²MOS), an advanced all ion-implanted process that combines fast CMOS logic and linear, bipolar circuits on a single chip, thus achieving excellent linear performance while retaining low CMOS power levels.

PRODUCT HIGHLIGHTS

1. Fast Conversion Time
   Fast, 3 μs and 10 μs conversion times make the AD7572A ideal for DSP applications and wideband data acquisition systems.
2. Wide Power Supply Range
   The AD7572A operates from 5 V and −12 V or −15 V power supplies.
3. Microprocessor Interface
   Fast, easy-to-use digital interface has three-state bus access times of 90 ns and bus relinquish times of 75 ns allowing the AD7572A to interface to most microprocessors.
4. Low Power
   LC²MOS circuitry gives low power drain (100 mW) from +5, −12 volt supplies.
5. 24-pin 0.3″ DIP and SOIC packages offer space saving over parts in 28-pin 0.6″ DIP.

NOTES

[1]Temperature ranges are as follows: J, L Versions, 0 to +70°C; A Version, −40°C to +85°C; S Version, −55°C to +125°C.

[2]Includes internal voltage reference error.

[3]Full-Scale TC = ΔFS/ΔT where ΔFS is Full-Scale change from T_A = +25°C to T_{min} or T_{max}.

[4]Includes internal voltage reference drift.

[5]Sample tested to ensure compliance.

[6]Power supply current is measured when the AD7572A is inactive, i.e., $\overline{CS}$ = $\overline{RD}$ = $\overline{BUSY}$ = HIGH.

Specifications subject to change without notice.

TIMING CHARACTERISTICS (V_{DD} = 5 V ± 5%, V_{SS} = −11.4 V to −16.5 V)

Parameter	Limit at +25°C (All Grades)	Limit at T_{min}, T_{max} (J, L, A Grades)	Limit at T_{min}, T_{max} (S Grade)	Units	Conditions/Comments
t_1	0	0	0	ns min	$\overline{CS}$ to $\overline{RD}$ Setup Time
t_2	190	230	270	ns max	$\overline{RD}$ to $\overline{BUSY}$ Propagation Delay

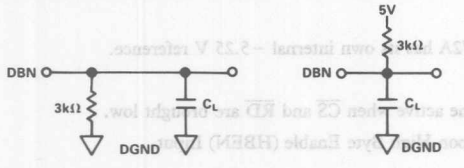
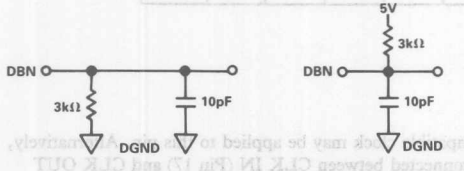
	75	85	90	ns max	
t_8	0	0	0	ns min	HBEN to $\overline{RD}$ Setup Time
t_9	0	0	0	ns min	HBEN to $\overline{RD}$ Hold Time
t_{10}	200	200	200	ns min	Delay Between Successive Read Operations



NOTE

[1]Timing Specifications are sample tested at +25°C to ensure compliance. All input control signals are specified with tr = tf = 5 ns (10% to 90% of +5 V) and timed from a voltage level of 1.6 V.

[2]t_3 and t_6 are measured with the load circuits of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.



[3]t_7 is defined as the time required for the data lines to change 0.5 V when loaded with the circuits of Figure 2.

Specifications subject to change without notice.

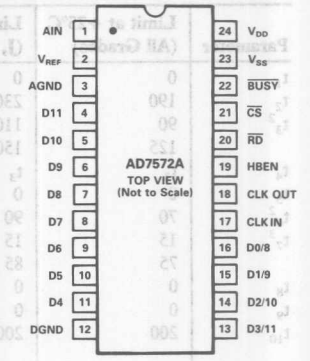
*Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other condition above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION:

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subjected to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The foam should be discharged to the destination socket before devices are removed.



ORDERING GUIDE

Model	Conversion Time	Temperature Range	Full-Scale TC	Accuracy Grade	Package Option[1]

NOTES
[1]N = Plastic DIP; Q = Cerdip; R = Small Outline IC (SOIC). For outline information see Package Information section.
[2]AD7572ASQ03 will be available to /883B processing only. Contact your local sales office for release information.

PIN CONFIGURATION

PIN FUNCTION DESCRIPTION

Pin No.	Mnemonic	Description
1	AIN	Analog Input.
2	V_{REF}	Voltage Reference Output. The AD7572A has its own internal −5.25 V reference.
3	AGND	Analog Ground.
4 . . . 11	D11 . . . D4	Three State Data Outputs. They become active when $\overline{CS}$ and $\overline{RD}$ are brought low.
13 . . . 16	D3/11 . . . D0/8	Individual pin function is dependent upon High Byte Enable (HBEN) Input.

DATA BUS OUTPUT, $\overline{CS}$ & $\overline{RD}$ = LOW

	Pin 4	Pin 5	Pin 6	Pin 7	Pin 8	Pin 9	Pin 10	Pin 11	Pin 13	Pin 14	Pin 15	Pin 16
MNEMONIC*	D11	D10	D9	D8	D7	D6	D5	D4	D3/11	D2/10	D1/9	D0/8
HBEN = LOW	DB11	DB10	DB9	DB8	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0
HBEN = HIGH	DB11	DB10	DB9	DB8	LOW	LOW	LOW	LOW	DB11	DB10	DB9	DB8

NOTES
*D11 . . . D0/8 are the ADC data output pins.
DB11 . . . DB0 are the 12-bit conversion results, DB11 is the MSB.

12	DGND	Digital Ground.
17	CLK IN	Clock Input Pin. An external TTL compatible clock may be applied to this pin. Alternatively, a crystal or ceramic resonator may be connected between CLK IN (Pin 17) and CLK OUT (Pin 18).
18	CLK OUT	Clock Output Pin. An inverted CLK IN signal appears at CLK OUT when an external clock is used. See CLK IN (Pin 17) description for crystal (resonator).
19	HBEN	High Byte Enable Input. Its primary function is to multiplex the 12 bits of conversion data onto the lower D7 . . . D0/8 outputs (4 MSBs or 8 LSBs). See Pin Description 4 . . . 11 and 13 . . . 16. It also disables conversion start when HBEN is high.
20	$\overline{RD}$	READ Input. This active LOW signal, in conjunction with $\overline{CS}$, is used to enable the output data three-state drivers and initiate a conversion if $\overline{CS}$ and HBEN are low.
21	$\overline{CS}$	CHIP SELECT Input. This active LOW signal, in conjunction with $\overline{RD}$ is used to enable the output data three-state drivers and initiate a conversion if $\overline{RD}$ and HBEN are low.
22	$\overline{BUSY}$	$\overline{BUSY}$ Output indicates converter status. $\overline{BUSY}$ is LOW during conversion.
23	V_{SS}	Negative Supply, −12 V to −15 V.
24	V_{DD}	Positive Supply, +5 V.

OPERATIONAL DIAGRAM

An operational diagram for the AD7572A is shown in Figure 3. The AD7572A is a 12-bit successive approximation A/D converter. The addition of just a crystal/ceramic resonator and a few capacitors enables the device to perform the analog-to-digital function.

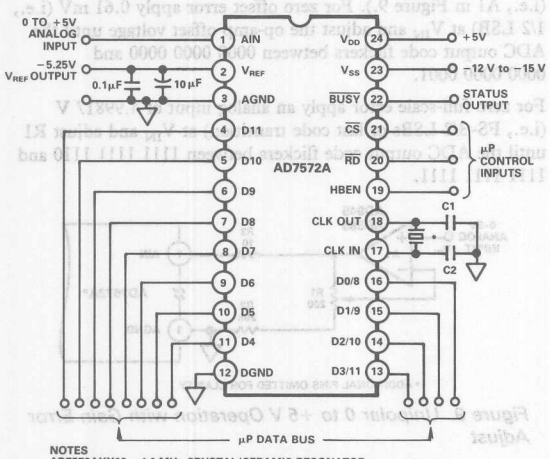

Figure 3. AD7572A Operational Diagram

CONVERTER DETAILS

Conversion start is controlled by the $\overline{CS}$, $\overline{RD}$ and HBEN inputs. At the start of conversion the successive approximation register (SAR) is reset and the three-state data outputs are enabled. Once a conversion cycle has begun it cannot be restarted.

During conversion, the internal 12-bit voltage mode DAC output is sequenced by the SAR from the most significant bit (MSB) to the least significant bit (LSB). Referring to Figure 4, the AIN input connects to the comparator input via 2.5 kΩ.

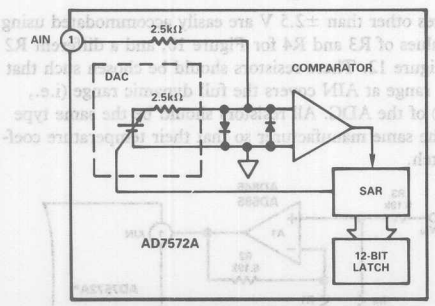

Figure 4. AD7572A AIN Input

The DAC which has a similar 2.5 kΩ output impedance connects to the same comparator input. Bit decisions are made by the comparator (zero crossing detector) which checks the addition of each successive weighted bit from the DAC output. The MSB decision is made 80 ns (typically) after the second falling edge of CLK IN following a conversion start. Similarly, the succeeding bit decisions are made approximately 80 ns after a CLK IN edge until conversion is finished. At the end of conversion, the DAC output current balances the AIN input current. The SAR contents (12-bit data word) which represent the AIN input signal is loaded into a 12-bit latch.

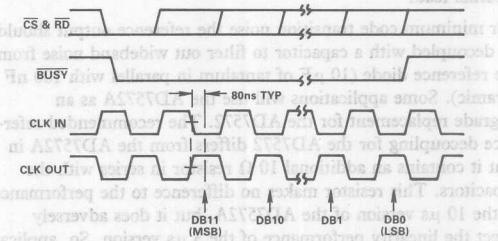

Figure 5. Operating Waveforms Using an External Clock Source for CLK IN

CONTROL INPUTS SYNCHRONIZATION

In applications where the $\overline{RD}$ control input is not synchronized with the ADC clock then conversion time can vary from 12 to 13 CLK IN periods. This is because the ADC waits for the first falling CLK IN edge after conversion start before the conversion procedure begins. Without synchronization, this delay can vary from zero to an entire clock period. If a constant conversion time is required, then the following approach ensures a fixed 3.125 µs conversion time for the AD7572AXX03 and 10 µs for the AD7572AXX10: when initiating a conversion, $\overline{RD}$ must go low on either the rising edge of CLK IN or the falling edge of CLK OUT.

DRIVING THE ANALOG INPUT

During conversion, the AIN input current is modulated by the DAC output current at a rate equal to the CLK IN frequency (i.e., 4 MHz when CLK IN = 4 MHz). The analog input voltage must remain fixed during this period and as a result must be driven from an op amp or sample-and-hold with a low output impedance. The output impedance of an op amp is equal to the open loop output impedance divided by the loop gain at the frequency of interest.

Suitable devices capable of driving the AD7572A AIN input are the AD845 op amp or the AD585 sample-and-hold.

INTERNAL CLOCK OSCILLATOR

Figure 6 shows the AD7572A internal clock circuit. A crystal or ceramic resonator may be connected between CLK IN (Pin 17) and CLK OUT (Pin 18) to provide a clock oscillator for the ADC timing. Alternatively the crystal/resonator may be omitted and an external clock source may be connected to CLK IN. For an external clock the mark/space ratio can vary from 45/55 to 55/45. An inverted CLK IN signal will appear at the CLK OUT pin as shown in the operating waveforms of Figure 5.

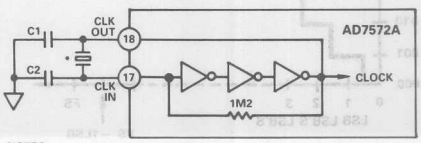

Figure 6. AD7572A Internal Clock Circuit

INTERNAL REFERENCE

The AD7572A has an on-chip, buffered, temperature-compensated, buried Zener reference, which is factory trimmed to −5.25 V ±1%. It is internally connected to the DAC and is also available at Pin 2 to provide up to 550 μA current to an external load.

For minimum code transition noise the reference output should be decoupled with a capacitor to filter out wideband noise from the reference diode (10 μF of tantalum in parallel with 100 nF ceramic). Some applications will use the AD7572A as an upgrade replacement for the AD7572. The recommended reference decoupling for the AD7572 differs from the AD7572A in that it contains an additional 10 Ω resistor in series with the capacitors. This resistor makes no difference to the performance of the 10 μs version of the AD7572A, but it does adversely affect the linearity performance of the 3 μs version. So, applications using the AD7572A as a 3 μs upgrade of the AD7572 must replace the 10 Ω reference resistor with a wire link.

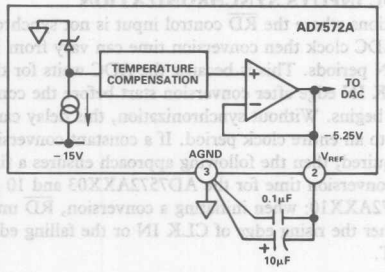

Figure 7. AD7572A Internal −5.25 V Reference

UNIPOLAR OPERATION

Figure 8 shows the ideal input/output characteristic for the 0 to 5 volt input range of the AD7572A. The designed code transitions occur midway between successive integer LSB values (i.e., 1/2 LSB, 3/2 LSBs, 5/2 LSBs . . . FS–3/2 LSBs). The output code is natural binary with 1 LSB = FS/4096 = (5/4096) V = 1.22 mV.

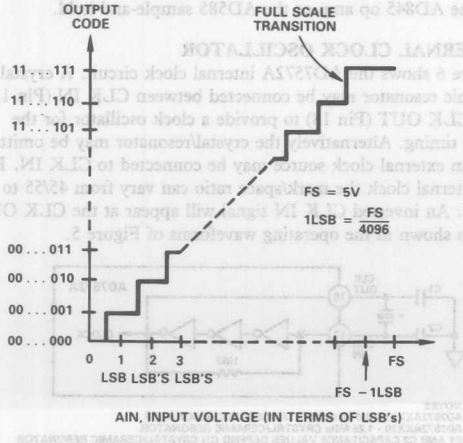

Figure 8. AD7572A Ideal Input/Output Transfer Characteristic

UNIPOLAR OFFSET AND FULL-SCALE ERROR ADJUSTMENT

In applications where absolute accuracy is important then offset and full-scale error can be adjusted to zero. Offset error must be adjusted before full-scale error. Figure 9 shows the extra components required for full-scale error adjustment. Zero offset is achieved by adjusting the offset of the op amp driving AIN (i.e., A1 in Figure 9.). For zero offset error apply 0.61 mV (i.e., 1/2 LSB) at V_{IN} and adjust the op-amp offset voltage until the ADC output code flickers between 0000 0000 0000 and 0000 0000 0001.

For zero full-scale error apply an analog input of 4.99817 V (i.e., FS–3/2 LSBs or last code transition) at V_{IN} and adjust R1 until the ADC output code flickers between 1111 1111 1110 and 1111 1111 1111.

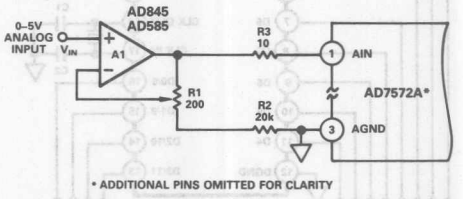

Figure 9. Unipolar 0 to +5 V Operation with Gain Error Adjust

BIPOLAR OPERATION

Figures 10 and 12 show how bipolar operation can be achieved with the AD7572A. Both circuits use an op amp to offset the analog signal (V_{IN}) by 2.5 V. Alternatively, the op amp (A1) can be replaced by a sample hold as shown in Figure 24. The op amp transfer functions are given below:

Figure 10: AIN = (V_{IN} + 2.5) volts
Figure 12: AIN = (−V_{IN} + 2.5) volts

Both circuits have an analog input range of ±2.5 V and an LSB size of 1.22 mV. The output codes are offset binary for Figure 10 and complementary offset binary for Figure 12. Their ideal input/output transfer characteristics after offset and full-scale adjustment are shown in Figures 11 and 13.

Signal ranges other than ±2.5 V are easily accommodated using different values of R3 and R4 for Figure 10, and a different R2 value for Figure 12. These resistors should be chosen such that the voltage range at AIN covers the full dynamic range (i.e., 0 V to 5 V) of the ADC. All resistors should be the same type and from the same manufacturer so that their temperature coefficients match.

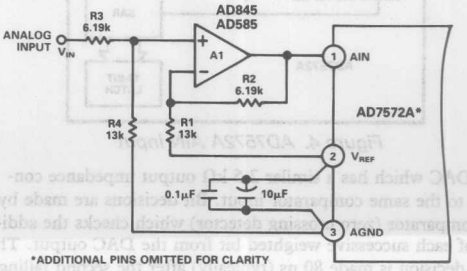

Figure 10. AD7572A Bipolar Operation – Output Code is Offset Binary

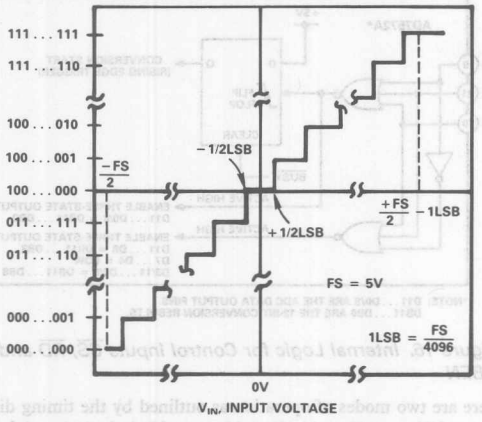

Figure 11. Ideal Input/Output Transfer Characteristic for the Bipolar Circuit of Figure 10

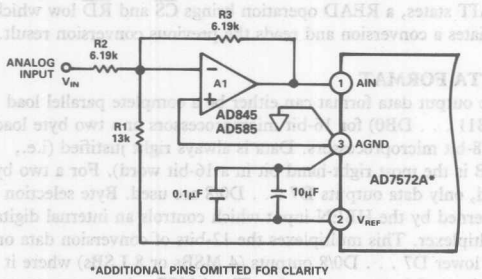

Figure 12. AD7572A Bipolar Operation - Output Code is Complementary Offset Binary

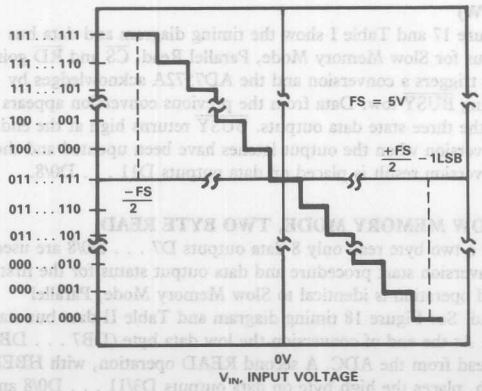

Figure 13. Ideal Input/Output Transfer Characteristic for the Bipolar Circuit of Figure 12

OFFSET AND FULL-SCALE ERROR

In most Digital Signal Processing (DSP) applications offset and full-scale error have little or no effect on system performance. A typical example is a digital filter, where an analog signal is quantized, digitally processed and recreated using a DAC. In these types of applications the offset error can be eliminated by ac coupling the recreated signal. Full-scale error effect is linear and does not cause problems as long as the input signal is within the full dynamic range of the ADC. An important parameter in DSP applications is Differential Nonlinearity and this is not affected by either offset or full-scale error.

In measurement applications where absolute accuracy is required, offset and full-scale error can be adjusted to zero as in Figure 14.

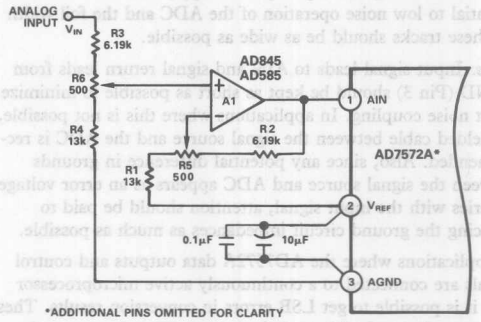

Figure 14. AD7572A Bipolar Operation with Offset and Gain Error Adjust

BIPOLAR OFFSET AND FULL-SCALE ERROR ADJUSTMENT

The bipolar circuit of Figure 10 can be adjusted for offset and full-scale errors, by including two potentiometers R5 and R6, as shown in Figure 14. Offset must be adjusted before full-scale error. This is achieved by applying an analog input of 0.61 mV (1/2 LSB) at V_{IN} and adjusting R5 until the ADC output code flickers between 1000 0000 0000 and 1000 0000 0001.

For full-scale error adjustment, the analog input must be at 2.49817 volts (i.e., FS/2 –3/2 LSBs or last transition point). Then R6 is adjusted until the ADC output code flickers between 1111 1111 1110 and 1111 1111 1111.

A similar offset and full-scale error adjustment procedure may be employed for Figure 12 by making R1 and R2 variable. Offset must again be adjusted before full scale error. This is achieved by applying an analog input of 0.61 mV at V_{IN} and adjusting R1 until the ADC output code flickers between 0111 1111 1110 and 0111 1111 1111.

For full-scale error adjustment, apply a signal source of 2.49817 V at V_{IN} and adjust R2 until the ADC output code flickers between 0000 0000 0000 and 0000 0000 0001.

APPLICATION HINTS

Wire wrap boards are not recommended for high resolution or high speed A/D converters. To obtain the best performance from the AD7572A a printed circuit board is required. Layout for the printed circuit board should ensure that digital and analog signal lines are separated as much as possible. In particular, care should be taken not to run any digital track alongside an analog signal track or underneath the AD7572A. The analog input should be screened by AGND.

A single point analog ground (STAR ground) separate from the logic system ground should be established at Pin 3 (AGND) or as close as possible to the AD7572A as shown in Figure 15. Pin 12 (AD7572A DGND) and all other analog grounds should be connected to this single analog ground point. No other digital grounds should be connected to this analog ground point. Low impedance analog and digital power supply common returns are essential to low noise operation of the ADC and the foil width for these tracks should be as wide as possible.

Noise: Input signal leads to AIN and signal return leads from AGND (Pin 3) should be kept as short as possible to minimize input noise coupling. In applications where this is not possible, a shielded cable between the signal source and the ADC is recommended. Also, since any potential difference in grounds between the signal source and ADC appears as an error voltage in series with the input signal, attention should be paid to reducing the ground circuit impedances as much as possible.

In applications where the AD7572A data outputs and control signals are connected to a continuously active microprocessor bus, it is possible to get LSB errors in conversion results. These errors are due to feedthrough from the microprocessor to the successive approximation comparator. The problem can be eliminated by forcing the microprocessor into a WAIT state during conversion (see Slow Memory Mode interfacing), or by using three-state buffers to isolate the AD7572A data bus.

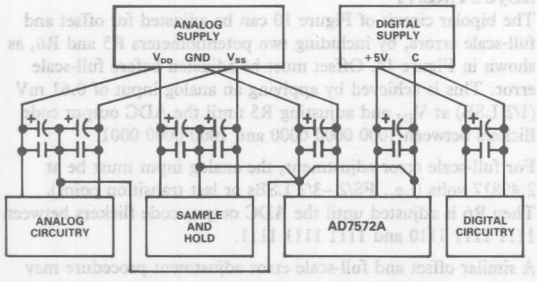

Figure 15. Power Supply Grounding Practice

TIMING AND CONTROL

Conversion start and data read operations are controlled by three AD7572A digital inputs; HBEN, $\overline{CS}$ and $\overline{RD}$. Figure 16 shows the logic structure associated with these inputs. The three signals are internally gated so that a logic "0" is required on all three inputs to initiate a conversion. Once initiated it cannot be restarted until conversion is complete. Converter status is indicated by the $\overline{BUSY}$ output, and this is low while conversion is in progress.

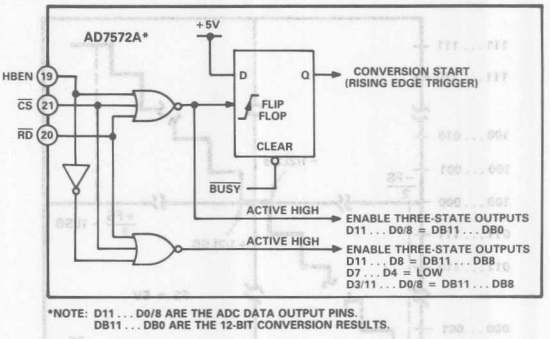

Figure 16. Internal Logic for Control Inputs $\overline{CS}$, $\overline{RD}$ and HBEN

There are two modes of operation as outlined by the timing diagrams of Figures 17 to 20. Slow Memory Mode is designed for microprocessors which can be driven into a WAIT state, a READ operation brings $\overline{CS}$ and $\overline{RD}$ low which initiates a conversion and data is read when conversion is complete. The second is the ROM Mode which does not require microprocessor WAIT states, a READ operation brings $\overline{CS}$ and $\overline{RD}$ low which initiates a conversion and reads the previous conversion result.

DATA FORMAT

The output data format can either be a complete parallel load (DB11 . . . DB0) for 16-bit microprocessors or a two byte load for 8-bit microprocessors. Data is always right justified (i.e., LSB is the most right-hand bit in a 16-bit word). For a two byte read, only data outputs D7 . . . D0/8 are used. Byte selection is governed by the HBEN input which controls an internal digital multiplexer. This multiplexes the 12-bits of conversion data onto the lower D7 . . . D0/8 outputs (4 MSBs or 8 LSBs) where it can be read in two read cycles. The 4 MSBs always appear on D11 . . . D8 whenever the three-state output drivers are turned on.

SLOW MEMORY MODE, PARALLEL READ (HBEN = LOW)

Figure 17 and Table I show the timing diagram and data bus status for Slow Memory Mode, Parallel Read. $\overline{CS}$ and $\overline{RD}$ going low triggers a conversion and the AD7572A acknowledges by taking $\overline{BUSY}$ low. Data from the previous conversion appears on the three state data outputs. $\overline{BUSY}$ returns high at the end of conversion when the output latches have been updated and the conversion result is placed on data outputs D11 . . . D0/8.

SLOW MEMORY MODE, TWO BYTE READ

For a two byte read only 8 data outputs D7 . . . D0/8 are used. Conversion start procedure and data output status for the first read operation is identical to Slow Memory Mode, Parallel Read. See Figure 18 timing diagram and Table II data bus status. At the end of conversion the low data byte (DB7 . . . DB0) is read from the ADC. A second READ operation, with HBEN high, places the high byte on data outputs D3/11 . . . D0/8 and disables conversion start. Note the 4MSBs appear on data outputs D11 . . . D8 during the two READ operations above.

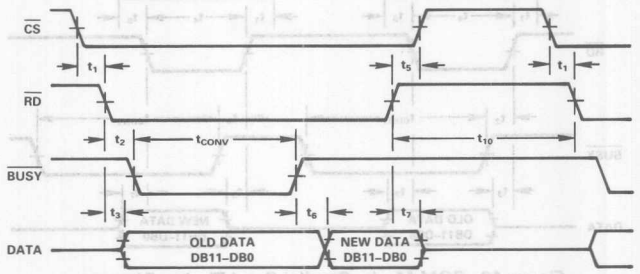

Figure 17. Slow Memory Mode, Parallel Read Timing Diagram

Table I. Slow Memory Mode, Parallel Read Data Bus Status

AD7572A Data Outputs	D11	D10	D9	D8	D7	D6	D5	D4	D3/11	D2/10	D1/9	D0/8
Read	DB11	DB10	DB9	DB8	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0

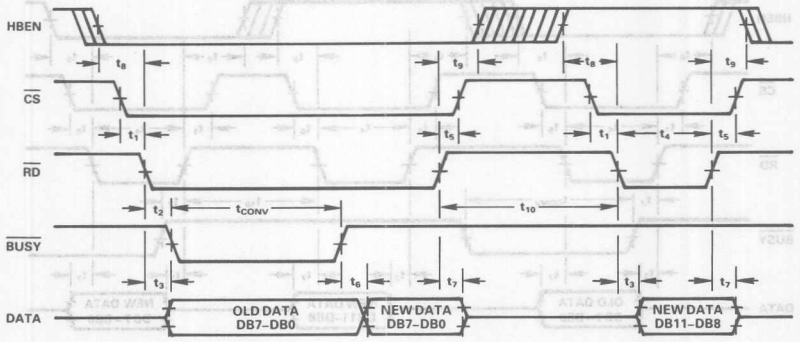

Figure 18. Slow Memory Mode, Two Byte Read Timing Diagram

Table II. Slow Memory Mode, Two Byte Read Data Bus Status

AD7572A Data Outputs	D7	D6	D5	D4	D3/11	D2/10	D1/9	D0/8
First Read	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0
Second Read	LOW	LOW	LOW	LOW	DB11	DB10	DB9	DB8

ROM MODE, PARALLEL READ (HBEN = LOW)

The ROM Mode avoids placing a microprocessor into a wait state. A conversion is started with a READ operation, and the 12-bits of data from the previous conversion are available on data outputs D11 . . . D0/8 (see Figure 19 and Table III). This data may be disregarded if not required. A second READ operation reads the new data (DB11 . . . DB0) and starts another conversion. A delay at least as long as the AD7572A conversion time must be allowed between READ operations.

ROM MODE, TWO BYTE READ

As previously mentioned for a two byte read, only data outputs D7 . . . D0/8 are used. Conversion is started in the normal way with a READ operation and the data output status is the same as the ROM Mode, Parallel Read. See Figure 20 timing diagram and Table IV data bus status. Two more READ operations are required to access the new conversion result. A delay equal to the AD7572A conversion time must be allowed between conversion start and the second data READ operation. The second READ operation, with HBEN high, disables conversion start and places the high byte (4 MSBs) on data outputs D3/11 . . . D0/8. A third READ operation accesses the low data byte (DB7 . . . DB0) and starts another conversion. The 4MSBs appear on data outputs D11 . . . D8 during all three read operations above.

Third Read	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0

MICROPROCESSOR INTERFACING

The AD7572A is designed to interface with microprocessors as a memory mapped device. The $\overline{CS}$ and $\overline{RD}$ control inputs are common to all peripheral memory interfacing. The HBEN input serves as a data byte select for 8-bit processors and is normally connected to the microprocessor address bus.

MC68000 Microprocessor

Figure 21 shows a typical interface for the 68000. The AD7572A is operating in the Slow Memory Mode. Assuming the AD7572A is located at address C000, then the following single 16-bit MOVE instruction both starts a conversion and reads the conversion result.

Move.W $C000,D0

At the beginning of the instruction cycle when the ADC address is selected, $\overline{BUSY}$ and $\overline{CS}$ assert $\overline{DTACK}$, so that the 68000 is forced into a WAIT state. At the end of conversion $\overline{BUSY}$ returns high and the conversion result is placed in the D0 register of the µP.

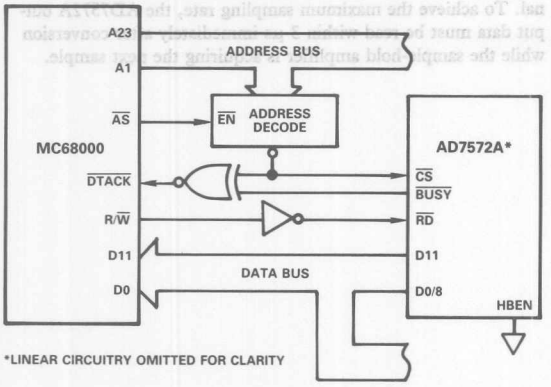

Figure 21. AD7572A–MC68000 Interface

8085A, Z80 MICROPROCESSOR

Figure 22 shows an AD7572A interface for the Z80 and 8085A. The AD7572A is operating in the Slow Memory Mode and a two byte read is required. Not shown in the figure is the 8-bit latch required to demultiplex the 8085A common address/data bus. A0 is used to assert HBEN, so that an even address (HBEN = LOW) to the AD7572A will start a conversion and read the low data byte. An odd address (HBEN = HIGH) will read the high data byte. This is accomplished with the single 16-bit LOAD instruction below.

For the 8085A LHLD (B000)
For the Z80 LD HL, (B000)

This is a two byte read instruction which loads the ADC data (address B000) into the HL register pair. During the first read operation, BUSY forces the microprocessor to WAIT for the AD7572A conversion. No WAIT states are inserted during the second read operation when the microprocessor is reading the high data byte.

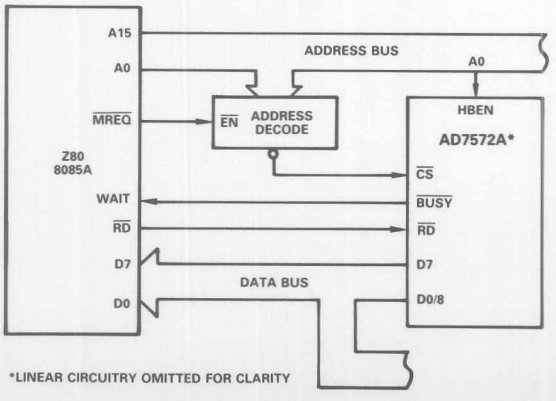

Figure 22. AD7572A–8085/Z80 Interface

TMS32010 MICROCOMPUTER

Figure 23 shows an AD7572A-TMS32010 interface. The AD7572A is operating in the ROM Mode. The interface is designed for a maximum TMS32010 clock frequency of 18 MHz but will typically work over the full TMS32010 clock frequency range.

The AD7572A is mapped at a port address. The following I/O instruction starts a conversion and reads the previous conversion result into data memory.

IN A,PA (PA = PORT ADDRESS)

When conversion is complete, a second I/O instruction reads the up-to-date data into data memory and starts another conversion. A delay at least as long as the ADC conversion time must be allowed between I/O instructions.

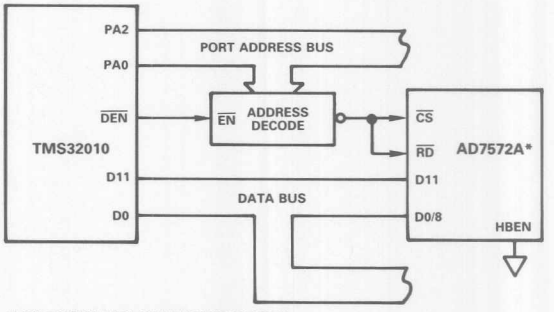

Figure 23. AD7572A–TMS32010 Interface

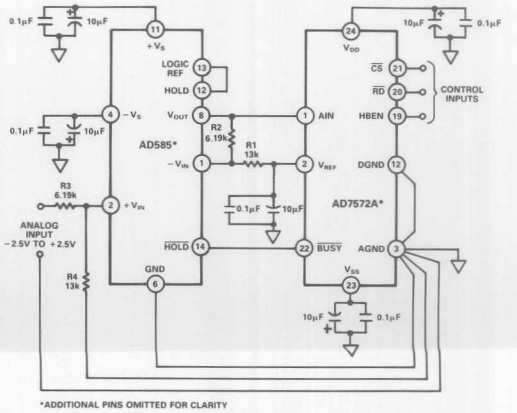
AD7572A–AD585 SAMPLE-HOLD INTERFACE

Figure 24 shows an AD585 sample-hold amplifier driving the AIN input of the AD7572A. The interface contains resistors R1, R2, R3 and R4 to allow a bipolar input signal range of ±2.5 volts. The maximum sampling frequency is 166 kHz for the AD7572AXX03 (3 μs conversion) and 77 kHz for the AD7572AXX10 (10 μs conversion). This includes the sample-hold amplifier acquisition time (3 μs).



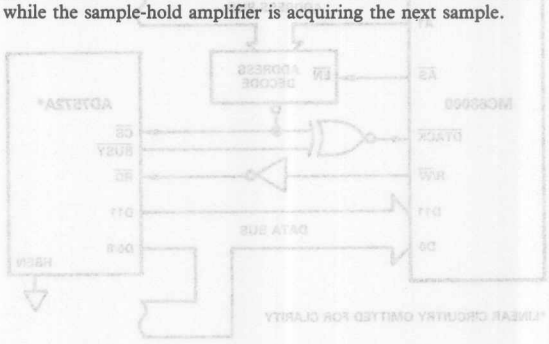


Figure 24. AD7572A–AD585 Sample-and-Hold Interface

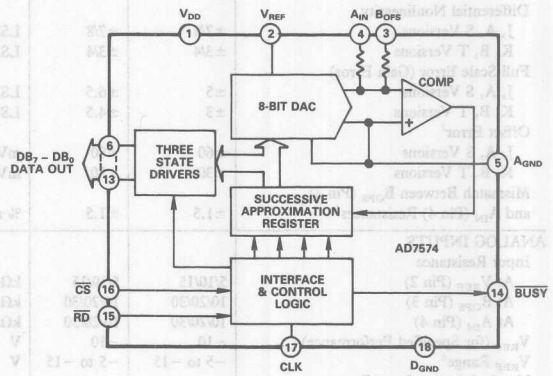
When an AD7572A conversion is initiated, the converter $\overline{BUSY}$ output goes low indicating conversion is in progress. The falling edge of this $\overline{BUSY}$ output signal places the sample-hold amplifier into the HOLD mode "freezing" the input signal to the AD7572A. When conversion is finished, the $\overline{BUSY}$ output returns HIGH allowing the sample-hold to track the input signal. To achieve the maximum sampling rate, the AD7572A output data must be read within 3 µs immediately after conversion while the sample-hold amplifier is acquiring the next sample.



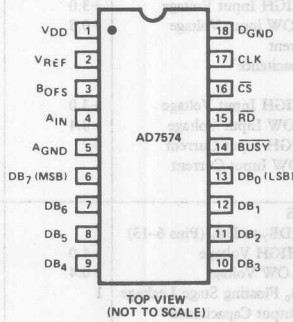
CMOS µP-Compatible 8-Bit ADC

AD7574

FEATURES

- 8-Bit Resolution
- No Missed Codes over Full Temperature Range
- Fast Conversion Time: 15µs
- Interfaces to µP like RAM, ROM or Slow - Memory
- Low Power Dissipation: 30mW
- Ratiometric Capability
- Single +5V Supply
- Low Cost
- Internal Comparator and Clock Oscillator

FUNCTIONAL BLOCK DIAGRAM



GENERAL DESCRIPTION

AD7574 is a low-cost, 8-bit µP compatible ADC which uses the successive-approximations technique to provide a conversion time of 15µs.

Designed to be operated as a memory mapped input device, the AD7574 can be interfaced like static RAM, ROM, or slow memory. Its $\overline{CS}$ (decoded device address) and $\overline{RD}$ ($\overline{READ}/\overline{WRITE}$ control) inputs are available in all µP memory systems. These two inputs control all ADC operations such as starting conversion or reading data. The ADC output data bits use three-state logic, allowing direct connection to the µP data bus or system input port.

Internal clock, +5V operation, on-board comparator and interface logic, as well as low power dissipation (30mW) and fast conversion time make the AD7574 ideal for most ADC/µP interface applications. Small size (18-pin DIP) and monolithic reliability will find wide use in avionics, instrumentation, and process automation applications.

NOTES

[1]Temperature ranges as follows: J, K, Versions, 0°C to +70°C; A, B Versions, −25°C to +85°C; S, T Versions; −55°C to +125°C.

[2]Typical offset temperature coefficient is ±150µV/°C.

[3]R_{BOFS}/R_{AIN} mismatch causes transfer function rotation about positive Full Scale. The effect is an offset and a gain term when using the circuit of Figure 9a.

[4]Typical value, not guaranteed or subject to test.

[5]Guaranteed but not tested.

Specifications subject to change without notice.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are Zener protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

This is a stress rating only and functional operation at or above this specification is not implied. Exposure to above maximum rating conditions for extended periods may affect device reliability.

TERMINOLOGY

RESOLUTION: Resolution is a measure of the *nominal* analog change required for a 1-bit change in the A/D converter's digital output. While normally expressed in a number of bits, the analog resolution of an n-bit unipolar A/D converter is (2^{-n}) V_{REF}). Thus, the AD7574, an 8-bit A/D converter, can resolve analog voltages as small as (1/256) (V_{REF}) when operated in a unipolar mode. When operated in a bipolar mode, the resolution is (1/128) (V_{REF}). Resolution does not imply accuracy. *Usable* resolution is limited by the differential nonlinearity of the A/D converter.

RELATIVE ACCURACY: Relative accuracy is the deviation of the ADC's actual code transition points from a straight line drawn between the devices' measured zero and measured full scale transition points. Relative accuracy, therefore, is a measure of code *position*.

DIFFERENTIAL NONLINEARITY: Differential nonlinearity in an ADC is a measure of the size of an anlog voltage range associated with any digitial output code. As such, differential nonlinearity specifies code width (usable resolution). An ADC with a specified differential nonlinearity of ±n bits will exhibit codes ranging in width from 1LSB −n LSB to 1LSB +n LSB. A specified differential nonlinearity of less than ±1LSB guarantees no-missing-codes operation.

ments for AD7574 operation as a static RAM.

A convert start is initiated by executing a memory WRITE instruction to the address location occupied by the AD7574 (once conversion has started, subsequent memory WRITES have no effect). A data READ is performed by executing a memory READ instruction to the AD7574 address location.

$\overline{BUSY}$ must be HIGH before a data READ is attempted, i.e. the total delay between a convert start and a data READ must be at least as great as the AD7574 conversion time. The delay

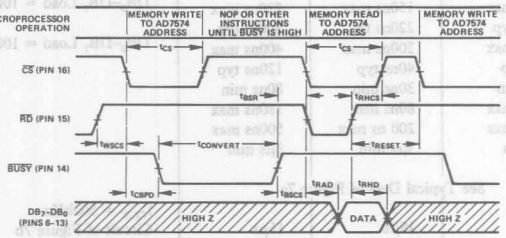

Figure 1. Static RAM Mode Timing Diagram

sion complete), a data READ is performed by executing a memory READ instruction to the address location occupied by the AD7574. The data readout is destructive, i.e. when RD returns HIGH, the converter is internally reset.

The RAM interface mode uses distinctly different commands to start conversion (memory WRITE) or read the data (memory READ). This is in contrast to the ROM mode where a memory READ causes a data READ *and* a conversion restart.

Table I. Truth Table, Static RAM Mode

AD7574 INPUTS		AD7574 OUTPUTS		AD7574 OPERATION
$\overline{CS}$	$\overline{RD}$	$\overline{BUSY}$	$DB_7 \cdot DB_0$	
L	H	H	HIGH Z	WRITE CYCLE (START CONVERT)
L	⊓	H	HIGH Z → DATA	READ CYCLE (DATA READ)
L	⊔	H	DATA → HIGH Z	RESET CONVERTER
H	X[1]	X	HIGH Z	NOT SELECTED
L	H	L	HIGH Z	NO EFFECT, CONVERTER BUSY
L	⊓	L	HIGH Z	NO EFFECT, CONVERTER BUSY
L	⊔	L	HIGH Z	NOT ALLOWED, CAUSES INCORRECT CONVERSION

Note 1: If $\overline{RD}$ goes LOW to HIGH when $\overline{CS}$ is LOW, the ADC is internally reset. $\overline{RD}$ has no effect while $\overline{CS}$ is HIGH. See application hint No. 1.

ROM INTERFACE MODE

Table II and Figure 2 show the truth table and timing requirements for interfacing the AD7574 like Read Only Memory.

$\overline{CS}$ is held LOW and converter operation is controlled by the $\overline{RD}$ input. The AD7574 $\overline{RD}$ input is derived from the decoded device address. MEMRD should be used to enable the address decoder in 8080 systems. VMA should be used to enable the address decoder in 6800 systems. A data READ is initiated by executing a memory READ instruction to the AD7574 address location. The converter is automatically restarted when $\overline{RD}$ returns HIGH. As in the RAM mode, attempting a data READ before $\overline{BUSY}$ is HIGH will result in incorrect data being read.

The advantage of the ROM mode is its simplicity. The major disadvantage is that the data obtained is relatively poorly defined in time inasmuch as executing a data READ automatically starts a new conversion. This problem can be overcome by executing two READs separated by NO-OPS (or other program instructions) and using only the data obtained from the second READ.

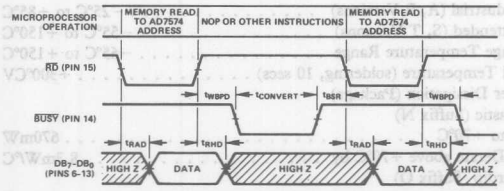

Figure 2. ROM Mode Timing Diagram ($\overline{CS}$ Held LOW)

Table II. Truth Table, ROM Mode

AD7574 INPUTS		AD7574 OUTPUTS		AD7574 OPERATION
$\overline{CS}$	$\overline{RD}$	$\overline{BUSY}$	$DB_7 \cdot DB_0$	
L	⊓	H	HIGH Z → DATA	DATA READ
L	⊔	H	DATA → HIGH Z	RESET AND START NEW CONVERSION
L	⊓	L	HIGH Z	NO EFFECT, CONVERTER BUSY
L	⊔	L	HIGH Z	NOT ALLOWED, CAUSES INCORRECT CONVERSION

SLOW-MEMORY INTERFACE MODE

Table III and Figure 3 show the truth table and timing requirements for interfacing the AD7574 as a slow-memory. This mode is intended for use with processors which can be forced into a WAIT state for at least 12μs (such as the 8080, 8085 and SC/MP). The major advantage of this mode is that it allows the μP to start conversion, WAIT, and then READ data with a single READ instruction.

In the slow-memory mode, $\overline{CS}$ and $\overline{RD}$ are tied together. It is suggested that the system ALE signal (8085 system) or SYNC signal (8080 system) be used to latch the address. The decoded device address is subsequently used to drive the AD7574 $\overline{CS}$ and $\overline{RD}$ inputs. $\overline{BUSY}$ is connected to the microprocessor READY input.

When the AD7574 is NOT addressed, the $\overline{CS}$ and $\overline{RD}$ inputs are HIGH. Conversion is initiated by executing a memory READ to the AD7574 address. $\overline{BUSY}$ subsequently goes LOW (forcing the μP READY input LOW) placing the μP in a WAIT state. When conversion is complete ($\overline{BUSY}$ is HIGH) the μP completes the memory READ.

Do not attempt to perform a memory WRITE in this mode, since three-state bus conflicts will arise.

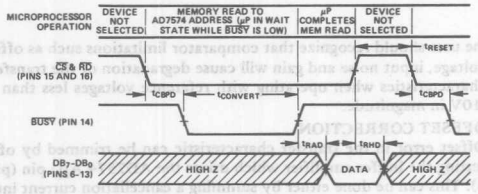

Figure 3. Slow Memory Mode Timing Diagram (CS and RD Tied Together)

Table III. Truth Table, Slow Memory Mode

AD7574 INPUTS	AD7574 OUTPUTS		AD7574 OPERATION

GENERAL CIRCUIT INFORMATION

BASIC CIRCUIT DESCRIPTION

The AD7574 uses the successive approximations technique to provide an 8-bit parallel digital output. The control logic was designed to provide easy interface to most microprocessors. Most applications require only passive clock components (R & C), a -10V reference, and +5V power.

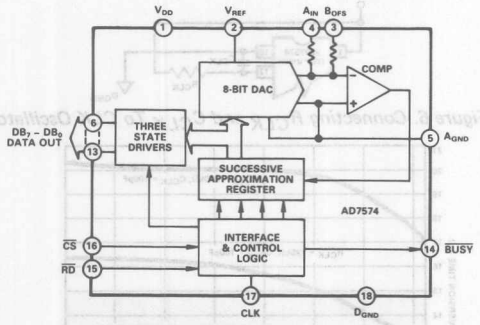

Figure 4. AD7574 Functional Diagram

Figure 4 shows the AD7574 functional diagram. Upon receipt of a start command either via the $\overline{CS}$ or $\overline{RD}$ pins, $\overline{BUSY}$ goes low indicating conversion is in progress. Successive bits, starting with the most significant bit (MSB) are applied to the input of a DAC. The comparator determines whether the addition of each successive bit causes the DAC output to be greater than or less than the analog input, A_{IN}. If the sum of the DAC bits is less than A_{IN}, the trial bit is left ON, and the next smaller bit is tried. If the sum is greater than A_{IN}, the trial bit is turned OFF and the next smaller bit is tried.

Each successively smaller bit is tried and compared to A_{IN} in this manner until the least significant bit (LSB) decision has been made. At this time $\overline{BUSY}$ goes HIGH (conversion is complete) indicating the successive approximation register contains a valid representation of the analog input. The $\overline{RD}$ control (see the previous page for details) can then be exercised to activate the three-state buffers, placing data on the DB_0 – DB_7 data output pins. $\overline{RD}$ returning HIGH causes the clock oscillator to run for 1 cycle, providing an internal ADC reset (i.e. the SAR is loaded with code 10000000).

DAC CIRCUIT DETAILS

The current weighting D/A converter is a precision multiplying DAC. Figure 5 shows the functional diagram of the DAC as used in the AD7574. It consists of a precision Silicon Chromium thin film R/2R ladder network and 8 N-channel MOSFET switches operated in single-pole-double-throw.

The currents in each 2R shunt arm are binarily weighted, i.e. the current in the MSB arm is V_{REF} divided by 2R, in the second arm is V_{REF} divided by 4R, etc. Depending on the DAC logic input (A/D output) from the successive approximation register, the current in the individual shunt arms is steered either to A_{GND} or to the comparator summing point.

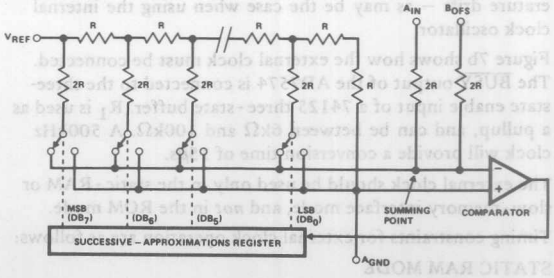

Figure 5. D/A Converter As Used In AD7574

OPERATING THE AD7574

APPLICATION HINTS

1. TIMING & CONTROL
   In the AD7574 when a conversion is finished the fresh data must be read before a new conversion can be started.
   Failure to observe the timing restrictions of Figures 1, 2 or 3 may cause the AD7574 to change interface modes. For example, in the RAM mode, holding $\overline{CS}$ LOW too long after $\overline{RD}$ goes HIGH will cause a new convert start (i.e. the converter moved into the ROM mode).
2. LOGIC DEGLITCHING IN uP APPLICATIONS
   Unspecified states on the address bus (due to different rise and fall times on the address bus) can cause glitches at the AD7574 $\overline{CS}$ or $\overline{RD}$ terminals. These glitches can cause unwanted convert starts, reads, or resets. The best way to avoid glitches is to gate the address decoding logic with RD or WR (8080) or VMA (6800) when in the ROM or RAM mode. When in the slow-memory mode, the ALE (8085) or SYNC (8080) signal should be used to latch the address.
3. INPUT LOADING AT V_{REF}, A_{IN} AND B_{OFS}
   To prevent loading errors due to the finite input resistance at the V_{REF}, A_{IN} or B_{OFS} pins, low impedance driving sources must be used (i.e. op amp buffers or low output-Z reference).
4. RATIOMETRIC OPERATION
   Ratiometric performance is inherent to A/D converters such as the AD7574 which use a multiplying DAC weighting network. However, the user should recognize that comparator limitations such as offset voltage, input noise and gain will cause degradation of the transfer characteristics when operating with reference voltages less than -10V in magnitude.
5. OFFSET CORRECTION
   Offset error in the transfer characteristic can be trimmed by offsetting the buffer amplifier which drives the AD7574 A_{IN} pin (pin 4). This can be done either by summing a cancellation current into the amplifier's summing junction, or by tapping a voltage divider which sits between V_{DD} and V_{REF} and applying the tap voltage to the amplifier's positive input (an example of a resistive tap offset adjust is shown in Figure 10a where R_8, R_9 and R_{10} can be used to offset the ADC).
6. ANALOG AND DIGITAL GROUND
   It is recommended that A_{GND} and D_{GND} be connected locally to prevent the possibility of injecting noise into the AD7574. In systems where the A_{GND}-D_{GND} intertie is not local, connect back-to-back diodes (IN914 or equivalent) between the AD7574 A_{GND} and D_{GND} pins.
7. INITIALIZATION AFTER POWER – UP
   Execute a memory READ to the AD7574 address location, and subsequently ignore the data. The AD7574 is internally reset when reading out data, i.e. the data readout is destructive.

CLOCK OSCILLATOR

The AD7574 has an internal asynchronous clock oscillator which starts upon receipt of a convert start command, and ceases oscillating when conversion is complete.

The clock oscillator requires an external R and C as shown in Figure 6. Nominal conversion times versus R_{CLK} and C_{CLK} is shown in Figure 7a. The curves shown in Figure 7a are applicable when operating in the RAM or slow-memory interface modes. When operating in the ROM interface mode, add 2μs to the typical conversion time values shown.

The AD7574 is guaranteed to provide transfer accuracy to published specifications for conversion times down to 15μs, as indicated by the unshaded region of Figure 7a. Conversion times faster than 15μs can cause transfer accuracy degradation.

OPERATION WITH EXTERNAL CLOCK

For applications requiring a conversion time close to or equal to 15μs, an external clock is recommended. Using an external clock precludes the possibility of converting faster than 15μs (which can cause transfer accuracy degradation) due to temperature drift – as may be the case when using the internal clock oscillator.

Figure 7b shows how the external clock must be connected. The $\overline{BUSY}$ output of the AD7574 is connected to the three-state enable input of a 74125 three-state buffer. R_1 is used as a pullup, and can be between 6kΩ and 100kΩ. A 500kHz clock will provide a conversion time of 15μs.

The external clock should be used only in the static-RAM or slow-memory interface mode, and *not* in the ROM mode.

Timing constraints for external clock operation are as follows:

STATIC RAM MODE

1. When initiating a conversion, $\overline{CS}$ should go LOW on a positive clock edge to provide optimum settling time for the MSB.
2. A data READ can be initiated any time after $\overline{BUSY}$ = 1.

SLOW-MEMORY MODE

1. When initiating a conversion, $\overline{CS}$ and $\overline{RD}$ should go LOW on a positive clock edge to provide optimum settling time for the MSB.

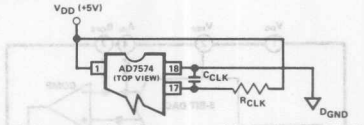

Figure 6. Connecting R_{CLK} and C_{CLK} To CLK Oscillator

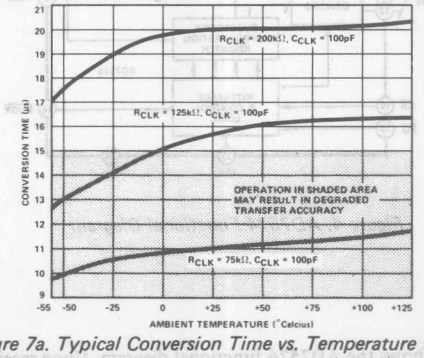

Figure 7a. Typical Conversion Time vs. Temperature For Different R_{CLK} and C_{CLK} (Applicable to RAM and Slow-Memory Modes. For ROM Mode add 2μs to values shown)

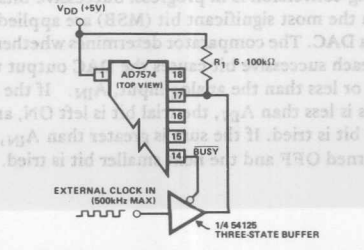

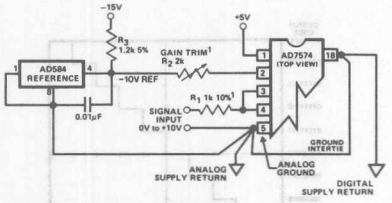

Figure 7b. External Clock Operation (Static RAM and Slow-Memory Mode)

Figures 8a and 8b show the analog circuit connections and typical transfer characteristic for unipolar operation. An AD584 is used as the -10V reference.

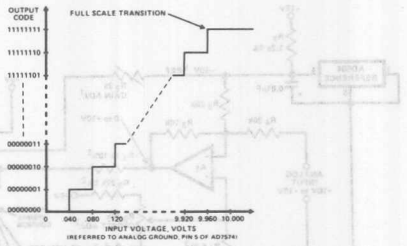
Calibration is as follows:

OFFSET

Offset must be trimmed out in the signal conditioning circuitry used to drive the signal input terminals shown in Figure 8a. An example of an offset trim is shown in Figure 10a, where R_8, R_9 and R_{10} comprise a simple voltage tap which is applied to the amplifier's positive input.

Note 1: R_1 and R_2 can be omitted if gain trim is not required

Figure 8a. AD7574 Unipolar (0V to +10V) Operation (Output Code is Straight Binary)



fier used to drive R_1 (i.e. +39.1mV at R_1).

2. While performing continuous conversions, adjust the offset potentiometer (described above) until DB_7 - DB_1 are LOW and the LSB (DB_0) flickers.

GAIN (FULL SCALE)

Offset adjustment must be performed before gain adjustment.

1. Apply -9.961V to the input of the buffer amplifier used to drive R_1 (i.e. +9.961V at R_1).
2. While performing continuous conversions, adjust trim pot R_2 until DB_7 - DB_1 are HIGH and the LSB (DB_0) flickers.

Note: Approximate bit weights are shown for illustration. Nominal bit weight for a -10V reference is ≈ 39.1mV

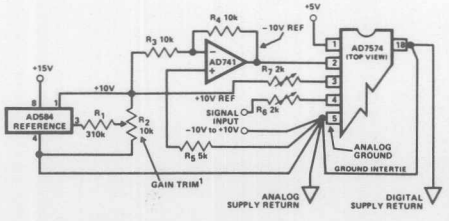


Figure 8b. Nominal Transfer Characteristic For Unipolar Circuit of Figure 8a

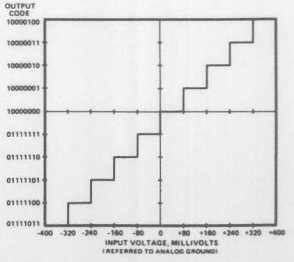
BIPOLAR (OFFSET BINARY) OPERATION

Figures 9a and 9b illustrate the analog circuitry and transfer characteristic for bipolar operation. Output coding is offset binary. As in unipolar operation, offset correction can be performed at the buffer amplifier used to drive the signal input terminals of Figure 9a (Resistors R_8, R_9 and R_{10} in Figure 10a show how offset trim can be done at the buffer amplifier).

Calibration is as follows:



1. Adjust R_6 and R_7 for minimum resistance across the potentiometers.
2. Apply +10.000V to the buffer amplifier used to drive the signal input (i.e. -10.000V at R_6).
3. While performing continuous conversions, trim R_6 or R_7 (whichever required) until DB_7 - DB_1 are LOW and the LSB (DB_0) flickers.

Note 1: R_1 and R_2 can be omitted if gain trim is not required

Figure 9a. AD7574 Bipolar (-10V to +10V) Operation (Output Code is Offset Binary)

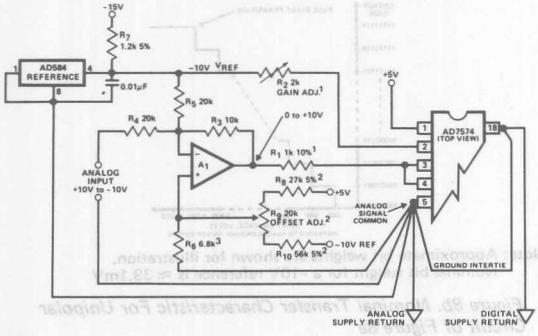
4. Apply 0V to the buffer amplifier used to drive the signal input terminals.
5. Doing continuous conversions, trim the offset circuit of the buffer amplifier until the ADC output code flickers between 01111111 and 10000000.
6. Apply +10.000V to the input of the buffer amplifier (i.e. -10.000V as applied to R_6).
7. Doing continuous conversions, trim R_2 until DB_7 - DB_1 are LOW and the LSB (DB_0) flickers.
8. Apply -9.922V to the input of the buffer amplifier (i.e. +9.922V at the input side of R_6).
9. If the ADC output code is not 11111110 ±1 bit, repeat the calibration procedure.

Note: Approximate bit weights are shown for illustration. Nominal bit weight for ± 10V full scale is ≈ 78.1mV

Figure 9b. Nominal Transfer Characteristic Around Major Carry for Bipolar Circuit of Figure 9a

BIPOLAR (COMPLEMENTARY OFFSET BINARY) OPERATION

Figure 10a shows the analog connections for complementary offset binary operation. The typical transfer characteristic is shown in Figure 10b. In this bipolar mode, the ADC is fooled into believing it is operated in a unipolar mode - i.e. the +10V to –10V analog input is conditioned into a 0 to +10V signal range. R_2 is the gain adjust, while R_9 is the offset adjust.

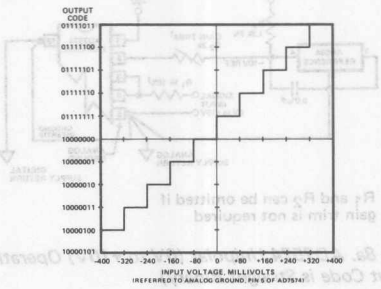


Calibration is as follows (adjust offset before gain):

OFFSET

1. Apply OV to the analog input shown in Figure 10a.
2. While performing continuous conversions, adjust R_9 until the converter output flickers between codes 01111111 and 10000000.

GAIN (FULL SCALE)



1. Apply –9.922V across the analog input terminals shown in Figure 10a.
2. While performing continuous conversions, adjust R_2 until DB_7 - DB_1 are HIGH and the LSB (DB_0) flickers between HIGH and LOW.

Notes:

1. R_1 and R_2 can be omitted if gain trim is not required
2. R_8, R_9 and R_{10} can be omitted if offset trim is not required
3. $R_6 \| R_8 \| R_{10} = 5k\Omega$. If R_8, R_9 and R_{10} not used, make $R_6 = 5k\Omega$

Figure 10a. AD7574 Bipolar Operation (–10V to +10V) (Output Code is Complementary Offset Binary)

Note: Approximate bit weights are shown for illustration. Nominal bit weight for ±10V full scale is ≈ 78.1mV

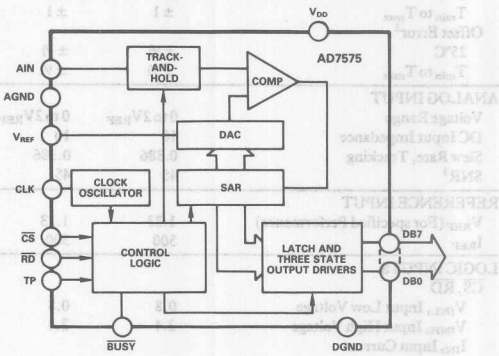


Figure 10b. Nominal Transfer Characteristic Around Major Carry for Bipolar Circuit of Figure 10a

LC²MOS
5μs 8-Bit ADC with Track/Hold
AD7575

FEATURES

- Fast Conversion Time: 5μs
- On-Chip Track/Hold
- Low Total Unadjusted Error: 1LSB
- Full Power Signal Bandwidth: 50kHz
- Single +5V Supply
- 100ns Data Access Time
- Low Power (15mW typ)
- Low Cost
- Standard 18-Pin DIPs or 20-Terminal Surface Mount Packages

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7575 is a high-speed 8-bit ADC with a built-in track/hold function. The successive approximation conversion technique is used to achieve a fast conversion time of 5μs, while the built-in track/hold allows full-scale signals up to 50kHz (386mV/μs slew rate) to be digitized. The AD7575 requires only a single +5V supply and a low-cost, 1.23V bandgap reference in order to convert an input signal range of 0 to $2V_{REF}$.

The AD7575 is designed for easy interfacing to all popular 8-bit microprocessors using standard microprocessor control signals ($\overline{CS}$ and $\overline{RD}$) to control starting of the conversion and reading of the data. The interface logic allows the AD7575 to be easily configured as a memory mapped device and the part can be interfaced as SLOW-MEMORY or ROM. All data outputs of the AD7575 are latched and three-state buffered to allow direct connection to a microprocessor data bus or I/O port.

The AD7575 is fabricated in an advanced, all ion-implanted high speed Linear Compatible CMOS (LC^2MOS) process and is available in a small, 0.3" wide, 18-pin DIP or in 20-terminal surface mount packages.

PRODUCT HIGHLIGHTS

1. Fast Conversion Time/Low Power
   The fast, 5μs conversion time of the AD7575 makes it suitable for digitizing wideband signals at audio and ultrasonic frequencies, while retaining the advantage of low CMOS power consumption.
2. On-Chip Track/Hold
   The on-chip track/hold function is completely self-contained and requires no external hold capacitor. Signals with slew rates up to 386mV/μs (e.g., 2.46V peak-to-peak 50kHz sine waves) can be digitized with full accuracy.
3. Low Total Unadjusted Error
   The zero, full-scale and linearity errors of the AD7575 are so low that the total unadjusted error at any point on the transfer function is less than 1LSB and offset and gain adjustments are not required.
4. Single Supply Operation
   Operation from a single +5V supply with a low-cost +1.23V bandgap reference allows the AD7575 to be used in 5V microprocessor systems without any additional power supplies.
5. Fast Digital Interface
   Fast interface timing allows the AD7575 to interface easily to the fast versions of most popular microprocessors such as the Z80H, 8085A-2, 6502B, 68B09 and the DSP processor, the TMS32010.

AD7575—SPECIFICATIONS (V_{DD} = +5V, V_{REF} = +1.23V, AGND = DGND = 0V; f_{CLK} = 4MHz external; All specifications T_{min} to T_{max} unless otherwise specified)

NOTES

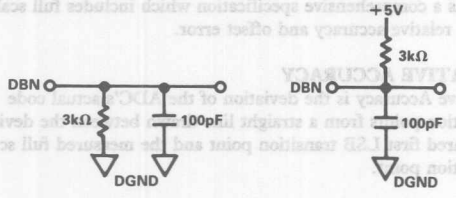
[1]Temperature Ranges are as follows:
J, K Versions; 0 to +70°C
A, B Versions; −25°C to +85°C
S, T Versions; −55°C to +125°C

[2]Offset error is measured with respect to an ideal first code transition which occurs at 1/2LSB.

[3]Sample tested at 25°C to ensure compliance.

[4]Accuracy may degrade at conversion times other than those specified.

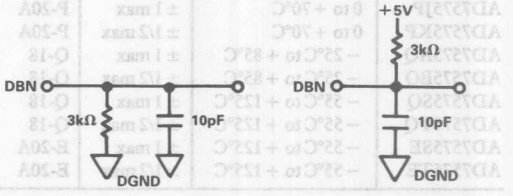
[5]Power supply current is measured when AD7575 is inactive i.e. when $\overline{CS}$ = $\overline{RD}$ = $\overline{BUSY}$ = logic HIGH.



Specifications subject to change without notice.

TIMING SPECIFICATIONS[1] (V_{DD} = +5V, V_{REF} = +1.23V, AGND = DGND = 0V)

Parameter	Limit at +25°C (All Versions)	Limit at T_{min}, T_{max} (J, K, A, B Versions)	Limit at T_{min}, T_{max} (S, T Versions)	Units	Conditions/Comments
t_1	0	0	0	ns min	$\overline{CS}$ to $\overline{RD}$ Setup Time
t_2	100	100	120	ns max	$\overline{RD}$ to $\overline{BUSY}$ Propagation Delay
t_3[2]	100	100	120	ns max	Data Access Time after $\overline{RD}$
t_4	100	100	120	ns min	$\overline{RD}$ Pulse Width
t_5	0	0	0	ns min	$\overline{CS}$ to $\overline{RD}$ Hold Time
t_6[2]	80	80	100	ns max	Data Access Time after $\overline{BUSY}$
t_7[3]	10	10	10	ns min	Data Hold Time
	80	80	100	ns max	
t_8	0	0	0	ns min	$\overline{BUSY}$ to $\overline{CS}$ Delay



NOTES
[1]Timing Specifications are sample tested at +25°C to ensure compliance. All input control signals are specified with tr = tf = 20ns (10% to 90% of +5V) and timed from a voltage level of 1.6V.
[2]t_3 and t_6 are measured with the load circuits of Figure 1 and defined as the time required for an output to cross 0.8V or 2.4V.
[3]t_7 is defined as the time required for the data lines to change 0.5V when loaded with the circuits of Figure 2.
Specifications subject to change without notice.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

TERMINOLOGY

LEAST SIGNIFICANT BIT (LSB)
An ADC with 8-bits resolution can resolve 1 part in 2^8 (i.e., 256) of full scale. For the AD7575 with +2.46V full scale one LSB is 9.61mV.

TOTAL UNADJUSTED ERROR
This is a comprehensive specification which includes full scale error, relative accuracy and offset error.

RELATIVE ACCURACY
Relative Accuracy is the deviation of the ADC's actual code transition points from a straight line drawn between the devices measured first LSB transition point and the measured full scale transition point.

SNR
Signal-to-Noise Ratio (SNR) is the ratio of the desired signal to the noise produced in the sampled and digitized analog signal. SNR is dependent on the number of quantization levels used in the digitization process; the more levels, the smaller the quantization noise. The theoretical SNR for a sine wave input is given by

SNR = (6.02N + 1.76)dB

where N is the number of bits in the ADC.

FULL SCALE ERROR (GAIN ERROR)
The gain of a unipolar ADC is defined as the difference between the analog input levels required to produce the first and the last digital output code transitions. Gain error is a measure of the deviation of the actual span from the ideal span of FS – 2LSB's.

ANALOG INPUT RANGE
With V_{REF} = +1.23V the maximum analog input voltage range is 0 to +2.46V. The output data in LSB's is related to the analog input voltage by the integer value of the following expression:

$$\text{Data (LSB's)} = \frac{256\ \text{AIN}}{2V_{REF}} + 0.5$$

SLEW RATE
Slew Rate is the maximum allowable rate of change of input signal such that the digital sample values are not in error. Slew Rate limitations may restrict the analog signal bandwidth for full-scale analog signals below the bandwidth allowed from sampling theorem considerations.

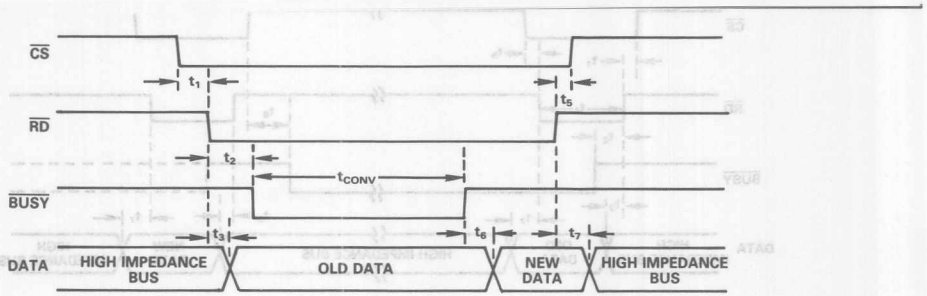

Figure 3. Slow Memory Interface Timing Diagram

TIMING AND CONTROL OF THE AD7575

The two logic inputs on the AD7575, $\overline{CS}$ and $\overline{RD}$, control both the starting of conversion and the reading of data from the part. A conversion is initiated by bringing both these control inputs LOW. Two interface options then exist for reading the output data from the AD7575. These are the Slow Memory Interface and ROM Interface and their operation is outlined below. It should be noted that the TP pin of the AD7575 must be hardwired HIGH to ensure correct operation of the part. This pin is used in testing the device and should not be used as a feedthrough pin in double-sided printed circuit boards.

SLOW MEMORY INTERFACE

The first interface option is intended for use with microprocessors which can be forced into a WAIT STATE for at least 5μs (such as the 8085A). The microprocessor starts a conversion and is halted until the result of the conversion is read from the converter. Conversion is initiated by executing a memory READ to the AD7575 address bringing $\overline{CS}$ and $\overline{RD}$ LOW. $\overline{BUSY}$ subsequently goes LOW (forcing the microprocessor READY input LOW) placing the processor into a WAIT state. The input signal, which had been tracked by the analog input, is held on the third falling clock edge of the input clock after $\overline{CS}$ and $\overline{RD}$ have gone LOW (see Figure 12). The AD7575 then performs a conversion on this acquired input signal value. When the conversion is complete ($\overline{BUSY}$ goes HIGH), the processor completes the memory READ and acquires the newly-converted data. The timing diagram for this interface is shown in Figure 3.

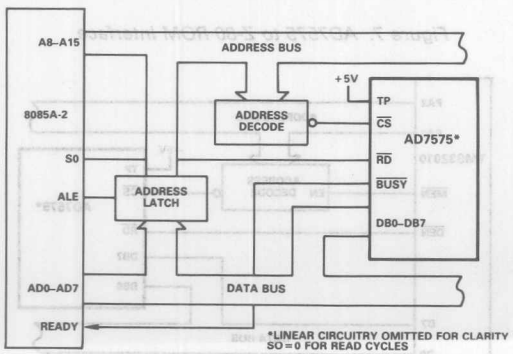

Figure 4. AD7575 to 8085A-2 Slow Memory Interface

The major advantage of this interface is that it allows the microprocessor to start conversion, WAIT and then READ data with a single READ instruction. The fast conversion time of the AD7575 ensures that the microprocessor is not placed in a WAIT state for an excessive amount of time.

Faster versions of many processors, including the 8085A-2, test the condition of the READY input very soon after the start of an instruction cycle. Therefore, $\overline{BUSY}$ of the AD7575 must go LOW very early in the cycle for the READY input to be effective in forcing the processor into a WAIT state. When using the 8085A-2, the processor S0 status signal provides the earliest possible indication that a READ operation is about to occur. Hence, S0 (which is LOW for a READ cycle) provides the READ signal to the AD7575. The connection diagram for the AD7575 to 8085A-2 Slow-Memory interface is shown in Figure 4.

ROM INTERFACE

The alternative interface option on the AD7575 avoids placing the microprocessor into a WAIT state. In this interface, a conversion is started with the first READ instruction and the second READ instruction accesses the data and starts a second conversion. The timing diagram for this interface is shown in Figure 5. It is possible to avoid starting another conversion on the second READ (see below).

Conversion is initiated by executing a memory READ instruction to the AD7575 address causing $\overline{CS}$ and $\overline{RD}$ to go LOW. Data is also obtained from the AD7575 during this instruction. This is old data and may be disregarded if not required. $\overline{BUSY}$ goes LOW indicating that conversion is in progress and returns HIGH when conversion is complete. Once again the input signal is held on the third falling edge of the input clock after $\overline{CS}$ and $\overline{RD}$ have gone LOW.

The $\overline{BUSY}$ line may be used to generate an interrupt to the microprocessor or monitored to indicate that conversion is complete. The processor then reads the newly-converted data. Alternatively, the delay between the convert start (first READ instruction) and the data READ (second READ instruction) must be at least as great as the AD7575 conversion time. For the AD7575 to operate correctly in the ROM interface mode $\overline{CS}$ and $\overline{RD}$ should not go LOW before $\overline{BUSY}$ returns HIGH.

Normally, the second READ instruction starts another conversion as well as accessing the output data. However, if $\overline{CS}$ and $\overline{RD}$ are brought LOW within one external clock period of $\overline{BUSY}$ going HIGH then a second conversion does not occur.

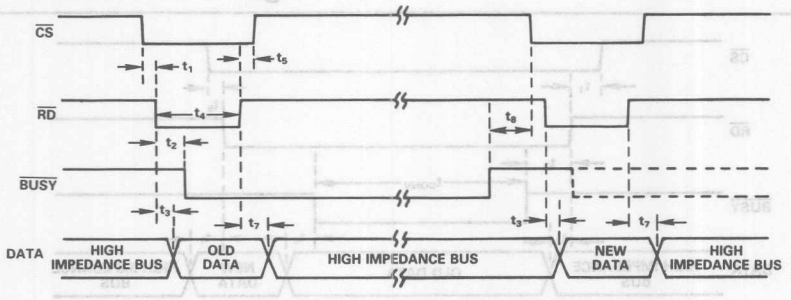

Figure 5. ROM Interface Timing Diagram

Figures 6 and 7 show connection diagrams for interfacing the AD7575 in the ROM Interface mode. Figure 6 shows the AD7575 interface to the 6502/6809 microprocessors while the connection diagram for interfacing to the Z-80 is shown in Figure 7.

As a result of its very fast interface timing the AD7575 can also be interfaced to the DSP processor, the TMS32010. The AD7575 will interface (within specifications) to the TMS32010 running at up to 18MHz but will typically work over the full clock frequency range of the TMS32010. Figure 8 shows the connection diagram for this interface. The AD7575 is mapped at a port address. Conversion is initiated using an IN A, PA instruction where PA is the decoded port address for the AD7575. The conversion result is obtained from the part using a second IN A, PA instruction and the resultant data is placed in the TMS32010 accumulator.

In many applications it is important that the signal sampling occurs at exactly equal intervals to minimize errors due to sampling uncertainty or jitter. The interfaces outlined previously require that for sampling at equi-distant intervals the user must count clock cycles or match software delays. This is especially difficult in interrupt driven systems where uncertainty in interrupt servicing delays would require that the AD7575 would have to have priority interrupt status and even then redundant software delays may be necessary to equalize loop delays.

This problem can be overcome by using a real time clock to control the starting of conversion. This can be derived from the clock source used to drive the AD7575 CLK pin. Since the sampling instant occurs three clock cycles after $\overline{CS}$ and $\overline{RD}$ go LOW then the input signal sampling intervals are equi-distant. The resultant data is placed in a FIFO latch which can be accessed by the microprocessor at its own rate whenever it requires the data. This ensures that data is not READ from the AD7575 during a conversion. If a data READ is performed during a conversion, valid data from the previous conversion will be accessed but the conversion in progress may be interfered with and an incorrect result is likely.

If $\overline{CS}$ and $\overline{RD}$ go LOW within 20ns of a falling clock edge the AD7575 may or may not see that falling edge as the first of the three falling clock edges to the sampling instant. In this case the sampling instant could vary by one clock period. If it is important to know the exact sampling instant, $\overline{CS}$ and $\overline{RD}$ should not go LOW within 20ns of a falling clock edge.

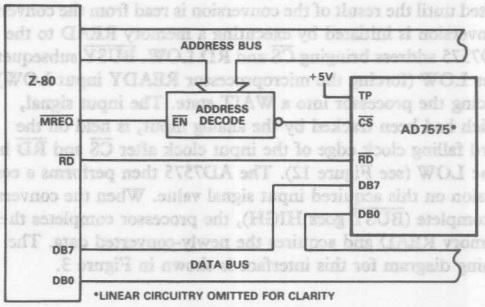

Figure 7. AD7575 to Z-80 ROM Interface

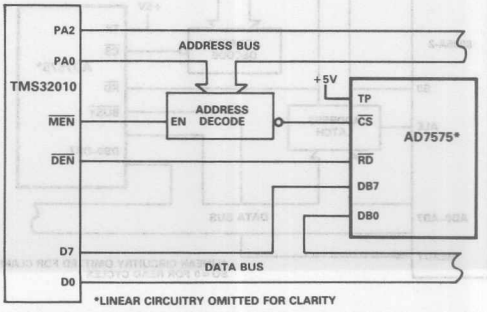

Figure 8. AD7575 to TMS32010 ROM Interface

A SAMPLED-DATA INPUT

The AD7575 makes use of a sampled-data comparator. The equivalent input circuit is shown in Figure 9. When a conversion starts, switch S1 is closed and the equivalent input capacitance is charged to V_{IN}. With a switch resistance of typically 500Ω and an input capacitance of typically 2pF the input time constant is 1ns. Thus C_{IN} becomes charged to within ±1/4LSB in 6.9 time constants or about 7ns. Since the AD7575 requires two input clock cycles (at a clock frequency of 4MHz) before going into the compare mode, there is ample time for the input voltage to settle before the first comparator decision is made. Increasing the source resistance increases the settling time required. Input bypass capacitors placed directly at the analog input act to average the input charging currents. The average current flowing through any source impedance can cause full-scale errors.

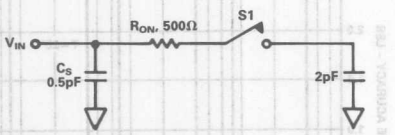

Figure 9. AD7575 Equivalent Input Circuit

REFERENCE INPUT

The reference input impedance on the AD7575 is code dependent and varies by a ratio of approximately 3-to-1 over the digital code range. The typical resistance range is from 6kΩ to 18kΩ. As a result of the code dependent input impedance, the V_{REF} input must be driven from a low impedance source. Figure 10 shows how an AD589 can be configured to produce a nominal reference voltage of +1.23V.

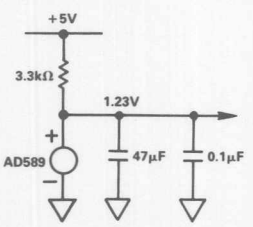

Figure 10. Reference Circuit

TRACK-AND-HOLD

The on-chip track-and-hold on the AD7575 means that input signals with slew rates up to 386mV/μs can be converted without error. This corresponds to an input signal bandwidth of 50kHz for a 2.46V peak-to-peak sine wave. Figure 11 shows a typical plot of signal-to-noise ratio versus input frequency, over the input bandwidth of the AD7575. The SNR figures are generated using a 200kHz sampling frequency and the reconstructed sine wave passes through a filter with a cutoff frequency of 50kHz.

The improvement in the SNR figures seen at the higher frequencies is due to the sharp cut-off of the filter (50kHz, 8th order Chebyshev) used in the test circuit.

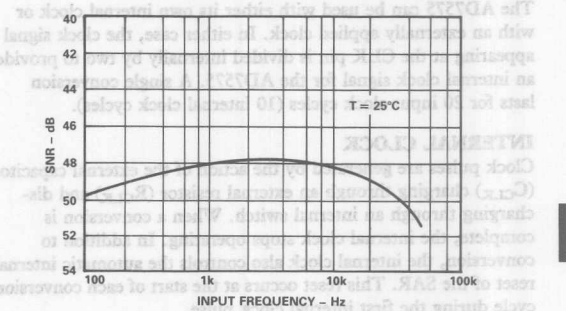

Figure 11. SNR vs. Input Frequency

The input signal is held on the third falling edge of the input clock after $\overline{CS}$ and $\overline{RD}$ go LOW. This is indicated in Figure 12 for the Slow Memory Interface. In between conversions the input signal is tracked by the AD7575 track-and-hold. Since the sampled signal is held on a small, on-chip capacitor it is advisable that the data bus be kept as quiet as possible during a conversion.

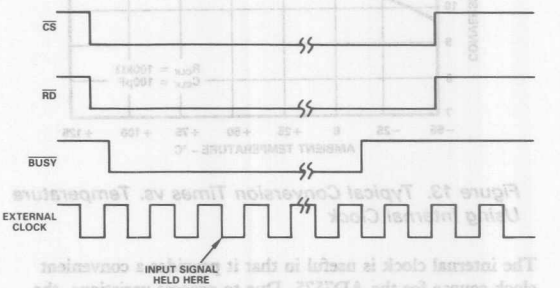

Figure 12a. Track-and-Hold (Slow Memory Interface) with External Clock

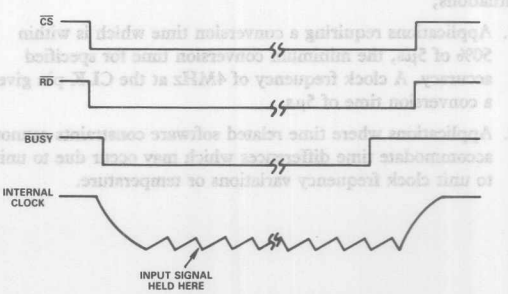

Figure 12b. Track-and-Hold (Slow Memory Interface) with Internal Clock

INTERNAL/EXTERNAL CLOCK

The AD7575 can be used with either its own internal clock or with an externally applied clock. In either case, the clock signal appearing at the CLK pin is divided internally by two to provide an internal clock signal for the AD7575. A single conversion lasts for 20 input clock cycles (10 internal clock cycles).

INTERNAL CLOCK

Clock pulses are generated by the action of the external capacitor (C_{CLK}) charging through an external resistor (R_{CLK}) and discharging through an internal switch. When a conversion is complete, the internal clock stops operating. In addition to conversion, the internal clock also controls the automatic internal reset of the SAR. This reset occurs at the start of each conversion cycle during the first internal clock pulse.

Nominal conversion times versus temperature for the recommended R_{CLK} and C_{CLK} combination are shown in Figure 13.

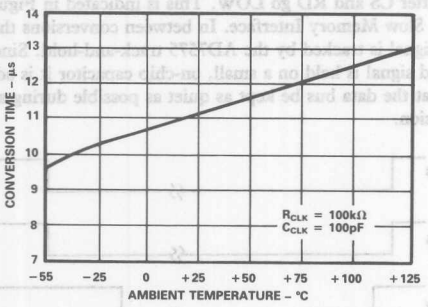

Figure 13. Typical Conversion Times vs. Temperature Using Internal Clock

The internal clock is useful in that it provides a convenient clock source for the AD7575. Due to process variations, the actual operating frequency for this R_{CLK}/C_{CLK} combination can vary from device to device by up to ±50%. For this reason it is recommended that an external clock be used in the following situations;

1. Applications requiring a conversion time which is within 50% of 5µs, the minimum conversion time for specified accuracy. A clock frequency of 4MHz at the CLK pin gives a conversion time of 5µs.
2. Applications where time related software constraints cannot accommodate time differences which may occur due to unit to unit clock frequency variations or temperature.

EXTERNAL CLOCK

The CLK input of the AD7575 may be driven directly from 74HC, 4000B series buffers (such as 4049) or from LS TTL with a 5.6kΩ pull-up resistor. When conversion is complete, the internal clock is disabled even if the external clock is still applied. This means that the external clock can continue to run between conversions without being disabled. The mark/space ratio of the external clock can vary from 70/30 to 30/70.

The AD7575 is specified for operation at a 5µs conversion rate with a 4MHz input clock frequency. If the part is operated at slower clock frequencies, it may result in slightly degraded accuracy performance from the part. This is a result of leakage effects on the hold capacitor. Figure 14 shows a typical plot of accuracy versus conversion time for the AD7575.

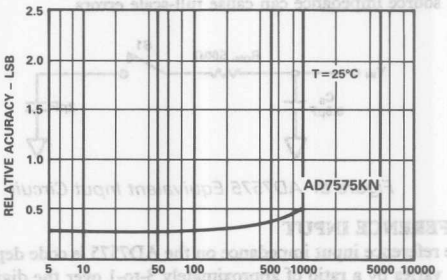

Figure 14. Accuracy vs. Conversion Time

UNIPOLAR OPERATION

The basic operation for the AD7575 is in the unipolar single supply mode. Figure 15 shows the circuit connections to achieve this while the nominal transfer characteristic for unipolar operation is given in Figure 16. Since the offset and full-scale errors on the AD7575 are very small, in many cases it will not be necessary to adjust out these errors. If calibration is required the procedure is as follows:

Offset Adjust

Offset error adjustment in single-supply systems is easily achievable by means of the offset null facility of an op-amp when used as a voltage follower for the analog input signal, AIN. The op-amp chosen should be able to operate from a single supply and allow a common-mode input voltage range that includes 0V (e.g., TLC271). To adjust for zero offset the input signal source is set to +4.8mV (i.e., 1/2LSB) while the op-amp offset is varied until the ADC output code flickers between 000 . . . 00 and 000 . . . 01.

Full Scale Adjust

The full scale or gain adjustment is made by forcing the analog input AIN to +2.445V (i.e., Full-Scale Voltage −3/2LSB). The magnitude of the reference voltage is then adjusted until the ADC output code flickers between 111 . . . 10 and 111 . . . 11.

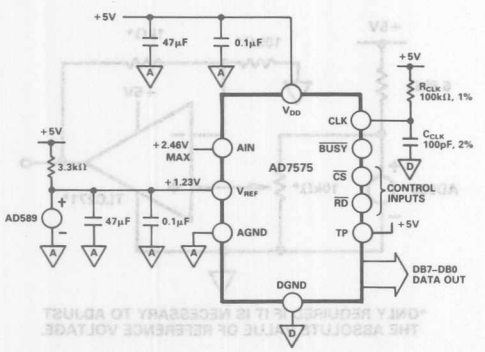

Figure 15. AD7575 Unipolar Configuration

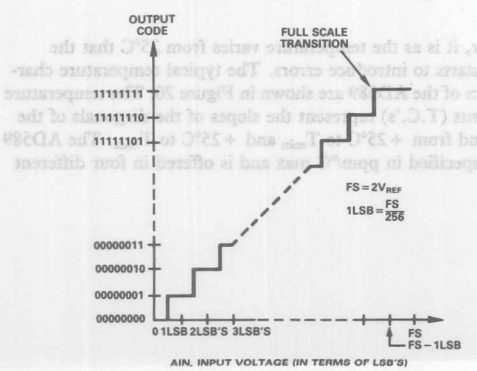

Figure 16. Nominal Transfer Characteristic for Unipolar Operation

BIPOLAR OPERATION

The circuit of Figure 17 shows how the AD7575 can be configured for bipolar operation. The output code provided by the AD7575 is offset binary. The analog input voltage range is ±5V, although the voltage appearing at the AIN pin of the AD7575 is in the range 0V to +2.46V. Figure 18 shows the transfer function for bipolar operation. The LSB size is now 39.06mV. Calibration of the bipolar operation is outlined below. Once again, because the errors are small it may not be necessary to adjust them. To maintain specified performance without the calibration all resistors should be 0.1% tolerance with R4 and R5 replaced by one 3.3kΩ resistor and R2 and R3 replaced by one 2.5kΩ resistor.

Offset Adjust

Offset error adjustment is achieved by applying an analog input voltage of −4.9805V (−FS +1/2LSB). Resistor R3 is then adjusted until the output code flickers between 000 . . . 00 and 000 . . . 01.

Full Scale Adjust

Full scale or gain adjustment is made by applying an analog input voltage of +4.9414V (+FS −3/2LSB). Resistor R4 is then adjusted until the output code flickers between 111 . . . 10 and 111 . . . 11.

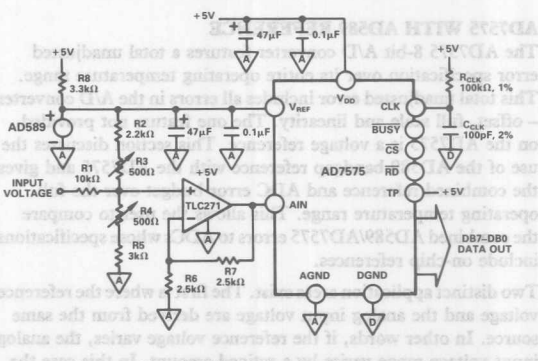

Figure 17. AD7575 Bipolar Configuration

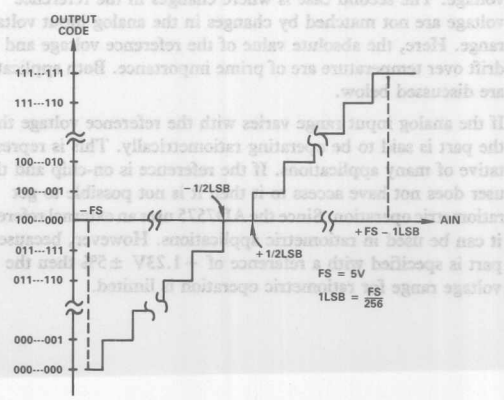

Figure 18. Nominal Transfer Characteristic for Bipolar Operation

APPLICATION HINTS

1. NOISE: Both the input signal lead to AIN, and the signal return lead from AGND should be kept as short as possible to minimize input-noise coupling. In applications where this is not possible, either a shielded cable or a twisted pair transmission line between source and ADC is recommended. Also, since any potential difference in grounds between the signal source and ADC appears as an error voltage in series with the input signal, attention should be paid to reducing the ground circuit impedance as much as possible. In general, the source resistance should be kept below 2kΩ. Larger values of source resistance can cause undesired system noise pickup.
2. PROPER LAYOUT: Layout for a printed circuit board should ensure that digital and analog lines are kept separated as much as possible. In particular, care should be taken not to run any digital track alongside an analog signal track. Both the analog input and the reference input should be screened by AGND. A single point analog ground which is separate from the logic system ground should be established at or near the AD7575. This single point analog ground subsystem should be connected to the digital system ground by a single-track connection only. Any reference bypass capacitors, analog input filter capacitors or input signal shielding should be returned to the analog ground point.

AD7575 WITH AD589 REFERENCE

The AD7575 8-bit A/D converter features a total unadjusted error specification over its entire operating temperature range. This total unadjusted error includes all errors in the A/D converter – offset, full scale and linearity. The one feature not provided on the AD7575 is a voltage reference. This section discusses the use of the AD589 bandgap reference with the AD7575 and gives the combined reference and ADC error budget over the full operating temperature range. This allows the user to compare the combined AD589/AD7575 errors to ADCs whose specifications include on-chip references.

Two distinct application areas exist. The first is where the reference voltage and the analog input voltage are derived from the same source. In other words, if the reference voltage varies, the analog input voltage range varies by a ratioed amount. In this case the user is not worried about the absolute value of the reference voltage. The second case is where changes in the reference voltage are not matched by changes in the analog input voltage range. Here, the absolute value of the reference voltage and its drift over temperature are of prime importance. Both applications are discussed below.

If the analog input range varies with the reference voltage then the part is said to be operating ratiometrically. This is representative of many applications. If the reference is on-chip and the user does not have access to it then it is not possible to get ratiometric operation. Since the AD7575 uses an external reference, it can be used in ratiometric applications. However, because the part is specified with a reference of +1.23V ±5% then the voltage range for ratiometric operation is limited.

The error analysis over temperature of ratiometric applications is different from nonratiometric ones. Since the reference and analog input voltage range are ratioed to each other, temperature variations in the reference are matched by variations in the analog input range. Therefore, the AD589 contributes no additional errors over temperature to the system errors and the combined total unadjusted error specification for the AD589 and AD7575 is as per the total unadjusted error specification in this data sheet.

With nonratiometric applications, however, the analog input range stays the same if the reference varies and a full-scale error is introduced. The amount which the reference varies determines the amount of error introduced. The AD589 is graded on temperature coefficient and therefore selection of different grades allows the user to tailor the amount of error introduced to suit the system requirements. The reference voltage from the AD589 can lie between 1.2V and 1.25V. This reference voltage can be adjusted for the desired full-scale voltage range using the circuit outlined in Figure 19. For example, if an analog input voltage range of 0 to +2.46V is required, the reference should be adjusted to +1.23V. Once the reference is adjusted to the desired value at 25°C the total error is as per the total unadjusted error specification on the AD7575 specification pages. (To reduce this even further, offset and full-scale errors of the AD7575 can be adjusted out using the calibration procedure outlined in this data sheet.)

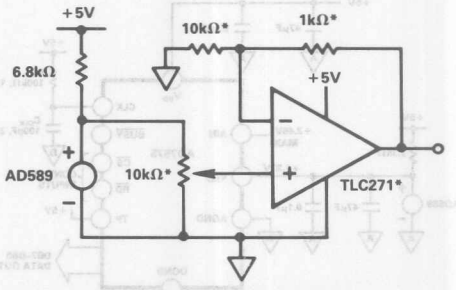

Figure 19. Reference Adjust Circuit

However, it is as the temperature varies from 25°C that the AD589 starts to introduce errors. The typical temperature characteristics of the AD589 are shown in Figure 20. The temperature coefficients (T.C.'s) represent the slopes of the diagonals of the error band from +25°C to T_{min} and +25°C to T_{max}. The AD589 T.C. is specified in ppm/°C max and is offered in four different grades.

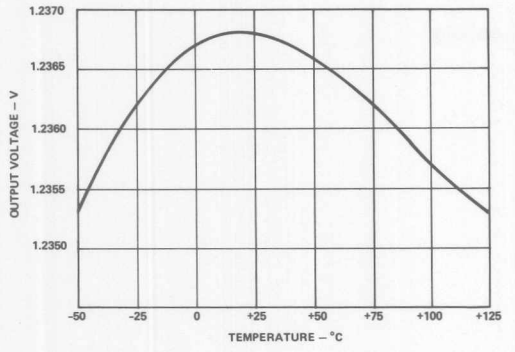

Figure 20. Typical AD589 Temperature Characteristics

The effect which the T.C. has on the system error is that it introduces a full-scale error in the ADC. This in turn affects the total unadjusted error specification. For example, using the AD589KH with a 50ppm/°C max T.C. the change in reference voltage from 25°C to 70°C is going to be from 1.23V to 1.22724V, a change of −2.76mV. This results in a change in the full-scale range of the ADC of −5.52mV, since the full-scale range on the AD7575 is $2V_{REF}$. Since the LSB size for the AD7575 is 9.61mV this means that the AD589 introduces an additional full-scale error of −0.57LSBs on top of the existing full-scale error specification for the ADC. Since the total unadjusted error specification for the ADC includes the full-scale error, there is also a corresponding increase in the total unadjusted error of −0.57LSBs. The change in reference voltage at 0°C is −1.5mV, resulting in a full-scale change of −3mV or −0.31LSBs worth of full-scale error. Table I shows the amount of additional total unadjusted error which is introduced by the temperature variation of the AD589, for different grades and for different temperature ranges. This table only applies to nonratiometric applications since the temperature variation of the reference does not affect the system error in ratiometric applications as outlined earlier. It shows the amount of error introduced over T_{min} to T_{max} for a system in which the reference has been adjusted to the desired value at 25°C. The final or right-most column of the table gives the total combined error for the AD589 and the top grade AD7575.

Taking the 25°C measurement as the starting point, the full-scale error introduced is always in the negative direction whether the temperature goes to T_{min} or T_{max}. This can be seen from the AD589 temperature characteristic shown in Figure 20. If the reference voltage is adjusted for 1.23V at 45°C (for the 0 to +70°C range) and 75°C (for the −55°C to +125°C range) the magnitude of the error introduced is reduced since it is distributed in both the positive and negative directions. Alternatively, this can be achieved, not by adjusting at these temperatures which would be impractical, but by adjusting the reference to 1.231V instead of 1.23V (for the extended temperature range) at 25°C. This has the required effect of distributing the plot of Figure 20 more evenly about the desired value.

An additional error source is the mismatch between the temperature coefficients (T.C.'s) of the 10kΩ and 1kΩ resistors in the feedback loop of the TLC271. If these resistors have ±50ppm/°C absolute T.C.'s then the worst case difference in drift between both resistors is 100ppm/°C. From +25°C to +125°C this introduces a worst case shift of 1.22mV which results in an additional full-scale error of 0.25LSB. If ±25ppm/°C resistors are used, then the worst case error is 0.13LSB. Over the 0 to +70°C range the ±50ppm/°C resistors introduce an additional full-scale error of 0.11LSB. All these errors are worst case and assume that the resistance values drift in opposite directions. In practice resistors of the same type and from the same manufacturer would drift in the same direction and hence the above error would be considerably reduced. An additional error source is the offset drift of the TLC271. This is only significant over the −55°C to +125°C range and even in this case it contributes <0.1LSB worth of full-scale error.

The error outlined in the right-hand column of Table I is a total unadjusted error specification excluding resistor and offset drift (the effect of these can be controlled by the user). It consists of errors from two error sources; a ±1LSB contribution from the AD7575 (including full-scale, offset and relative accuracy errors) and the remainder is a full-scale error introduced by the AD589. It is important to note that the variation of the AD589 voltage only introduces a full-scale error and that the relative accuracy (or endpoint nonlinearity) of the system, with a top grade AD7575, is still ±1/2LSB (i.e. 8-bits accurate).

AD589 Grade	Temperature Range (°C)	Full-Scale Error Introduced by AD589 @ T_{max} (Worst Case) (LSBs)	Combined Worst Case AD589/AD7575 T.U.E. @ T_{max} (LSBs)
AD589JH	0 to +70	−1.15	−2.15

CMOS 12-Bit Successive Approximation ADC

AD7578

FEATURES

- 12-Bit Successive Approximation ADC
- No Missed Codes Over Full Temperature Range
- Low Total Unadjusted Error ±1LSB max
- High Impedance Analog Input
- Autozero Cycle for Low Offset Voltage
- Low Power, 75mW typ
- Small Size: 0.3", 24-Pin Package
- Conversion Time of 100μs

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7578 is a medium speed, monolithic 12-bit CMOS A/D converter which uses the successive approximation technique to provide a conversion time of 100μs. An auto-zero cycle occurs at the start of each conversion resulting in very low system offset voltages, typically less than 100μV. The device is designed for easy microprocessor interfacing using standard control signals; $\overline{CS}$ (decoded device address), $\overline{RD}$ ($\overline{READ}$) and $\overline{WR}$ ($\overline{WRITE}$).

Conversion results are available in two bytes, 8LSBs and 4MSBs, over an 8-bit three state output bus. Either byte can be read first. Two converter busy flags are available to facilitate polling of the converter's status.

The analog input voltage range is 0V to +5V when using a reference voltage of +5V.

PRODUCT HIGHLIGHTS

1. The AD7578 is a complete 12-bit A/D converter in a 24-pin package requiring only a few passive components and a voltage reference.
2. Autozero cycle realizes very low offset voltages, typically 100μV.
3. Standard microprocessor control signals to allow easy interfacing to most popular 8- and 16-bit microprocessors.
4. Monolithic construction for increased reliability and small 0.3", 24-pin package.

	130	160	180	ns max	(Bus Relinquish Time)

NOTES
[1]Timing Specifications are sample tested at +25°C to ensure compliance. All input control signals are specified with $t_r = t_f = 20$ns (10% to 90% of +5V) and timed from a voltage level of +1.6V. Data is timed from V_{OH}, V_{OL}.
[2]When using an external clock source the $\overline{WR}$ pulse width must be extended to provide the minimum auto-zero cycle time of 10μs. See "External Clock Operation".
[3]t_{11} is measured with the load circuits of Figure 3 and defined as the time required for an output to cross 0.8V or 2.4V.
[4]t_{12} is defined as the time required for the data lines to change 0.5V when loaded with the circuits of Figure 4.
Specifications subject to change without notice.

Commercial (K Version)	0 to +70°C
Industrial (B Version)	−25°C to +85°C
Extended (T Version)	−55°C to +125°C
Storage Temperature	−65°C to +150°C
Lead Temperature (Soldering, 10secs)	+300°C
Power Dissipation (Any Package) to +75°C	1,000mW
Derate above +75°C by	10mW/°C

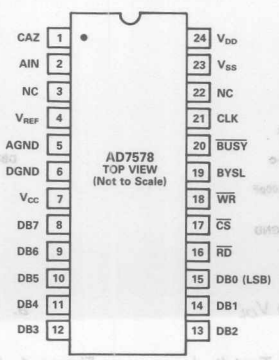
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

ORDERING GUIDE

Model[1, 2]	Temperature Range	Total Unadjusted Error T_{MIN} −T_{MAX}	Package Option[3]
AD7578KN	0°C to +70°C	±1LSB	N-24
AD7578BD	−25°C to +85°C	±1LSB	D-24A
AD7578TD	−55°C to +125°C	±1LSB	D-24A



NOTES

[1]Analog Devices reserves the right to ship either ceramic (D-24A) or cerdip (Q-24) hermetic packages.

[2]To order MIL-STD-883 Class B processed parts, add /883B to part number. Contact local sales office for military data sheet.

[3]D = Ceramic DIP; N = Plastic DIP. For outline information see Package Information section.

DIP PIN CONFIGURATION

NC = NO CONNECT

PIN	MNEMONIC	DESCRIPTION
1	CAZ	Autozero Capacitor Input. Connect other side of capacitor to AGND.
2	AIN	Analog Input
3	N/C	No Connect pin
4	V_{REF}	Voltage reference input. The AD7578 is specified with $V_{REF} = +5.0V$.
5	AGND	Analog Ground
6	DGND	Digital Ground
7	V_{CC}	Logic Supply. For $V_{CC} = +5V$ digital inputs and outputs are TTL compatible.
8-15		Three state data outputs. They become active when $\overline{CS}$ & $\overline{RD}$ are brought low. Individual pin function is dependent upon the Byte Select (BYSL) input.

DATA BUS OUTPUT, $\overline{CS}$ & $\overline{RD}$ = LOW

	BYSL = HIGH	BYSL = LOW
Pin 8	BUSY[1]	DB7
Pin 9	LOW[2]	DB6
Pin 10	LOW[2]	DB5
Pin 11	LOW[2]	DB4
Pin 12	DB11 (MSB)	DB3
Pin 13	DB10	DB2
Pin 14	DB9	DB1
Pin 15	DB8	DB0 (LSB)

[1]BUSY (Pin 8) is a converter status flag and is HIGH during a conversion.
[2]Pins 9-11 output a logic LOW when BYSL is HIGH.
DB11–DB0 are the 12-bit conversion results, DB11 is the MSB.

16	$\overline{RD}$	READ input. This active LOW signal, in combination with $\overline{CS}$, is used to enable the output data three-state drivers.
17	$\overline{CS}$	CHIP SELECT Input. Decoded device address, active LOW. Used in combination with either $\overline{RD}$ or $\overline{WR}$ for control.
18	$\overline{WR}$	WRITE Input. This active LOW signal, in combination with $\overline{CS}$, is used to start a new conversion. When the AD7578 internal clock is used, the minimum $\overline{WR}$ pulse width is t2 (INT). When an external clock source is used, the minimum $\overline{WR}$ pulse width must be extended to include the autozero cycle time. For external clock operation, the minimum $\overline{WR}$ pulse width is t2 (EXT).
19	BYSL	BYTE SELECT. This control input determines whether the high or low byte of data is placed on the output data bus during a data READ operation ($\overline{CS}$ & $\overline{RD}$ LOW). See description of pins 8-15.
20	$\overline{BUSY}$	BUSY indicates converter status. $\overline{BUSY}$ is LOW during conversion, otherwise $\overline{BUSY}$ is held at a logic HIGH.
21	CLK	CLOCK Input for internal/external clock operation. Internal : Connect R_{CLK} and C_{CLK1}/C_{CLK2} timing components. See Figure 6 and Figure 7. External : Connect external 74HC compatible clock source as shown in Figure 8.
22	N/C	No connect pin.
23	V_{SS}	Negative supply, −5V.
24	V_{DD}	Positive supply, +15V.

Operating Information

OPERATIONAL DIAGRAM

An operational diagram for the AD7578 is shown in Figure 5. The only passive components required are the autozero capacitor C_{AZ} and timing components R_{CLK}, C_{CLK1} & C_{CLK2} for the internal clock oscillator. If the AD7578 is to be used with an external clock source, then only C_{AZ} is required. Individual pin functions are described in detail on the previous page.

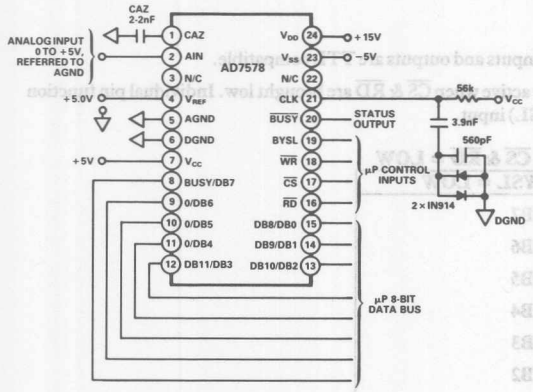


Figure 5. AD7578 Operational Diagram

INTERNAL CLOCK OPERATION

The clock circuitry for internal clock operation is shown in Figure 6 and the AD7578 operating waveforms are shown in Figure 7.

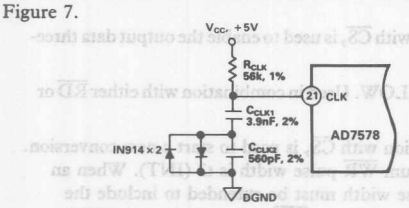

Figure 6. Circuitry Required for Internal Clock Operation

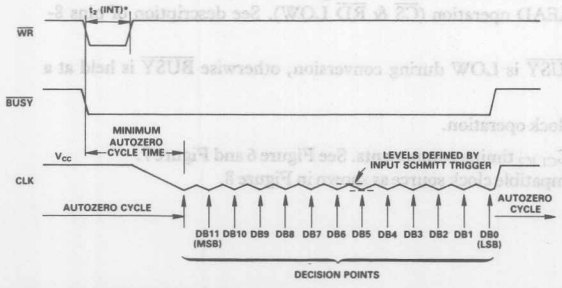

Figure 7. Operating Waveforms – Internal Clock

Between conversions ($\overline{BUSY}$ = HIGH) the AD7578 is in the autozero cycle. When $\overline{WR}$ goes LOW (with $\overline{CS}$ LOW) to start a new conversion, the autozero capacitor C_{AZ} charges to AIN – V_{OS} where V_{OS} is the input offset voltage of the autozero comparator.

A minimum time of 10µs is required for this autozero cycle. In applications using the internal clock oscillator, it is not necessary for $\overline{WR}$ to remain LOW for this period of time since it is automatically provided by the AD7578. This is achieved by switching a constant current load across the clock capacitors, C_{CLK1} and C_{CLK2}, causing the voltage at the CLK input pin to slowly decay from V_{CC}. This occurs after $\overline{WR}$ returns HIGH. The Schmitt trigger circuit monitoring the voltage on the CLK input ends the autozero cycle when its LOW input trigger level is reached. At this point, the constant current load across the clock capacitors is removed allowing them to charge towards V_{CC} via R_{CLK}. When the voltage at the CLK input reaches the HIGH trigger level, the constant current load is replaced across C_{CLK1} and C_{CLK2}. The MSB decision is made when the LOW trigger level is reached. This cycle repeats itself 12 times to provide 12 clock pulses for the conversion cycle. The circuit arrangement of Figure 6 provides the relatively slow autozero cycle time at the beginning of a conversion while allowing the clock oscillator to speed up once the autozero cycle is complete.

EXTERNAL CLOCK OPERATION

For external clock operation R_{CLK}, C_{CLK1} and C_{CLK2} are discarded and the CLK input is driven from a 74HC compatible clock source. The mark/space ratio of the external clock can vary from 40/60 to 60/40. The AD7578 $\overline{WR}$ pulse width must now be extended to provide the minimum autozero cycle time of 10µs since this is no longer provided automatically by the AD7578. Referring to the operating waveforms of Figure 9, the minimum $\overline{WR}$ pulse width when using an external clock source is t_2 (EXT). The $\overline{CS}$ input must now remain valid for the extended $\overline{WR}$ pulse width. One approach to stretching the available µP signals is shown in the general 8-bit µP interface circuit of Figure 20. It is not necessary to synchronize the external clock source with the extended $\overline{WR}$ pulse width, the MSB decision being made on the second falling edge of the clock input after the $\overline{WR}$ input returns HIGH.

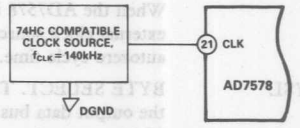

Figure 8. External Clock Operation

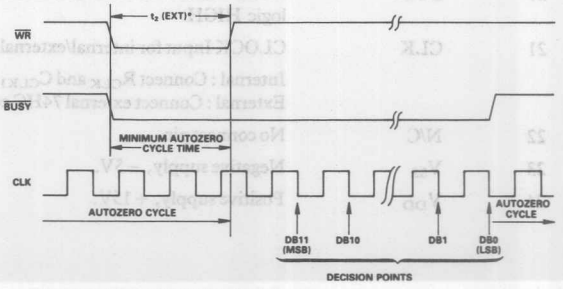

Figure 9. Operating Waveforms – External Clock

READING DATA

The 12-bit conversion data plus a converter status flag are available over an 8-bit wide data bus. Data is transferred from the AD7578 in right-justified format (i.e., the LSB is the most right-hand bit in a 16-bit word). Two READ operations are required, the Byte Select (BYSL) input determining which byte–8 least significant bits or 4 most significant bits plus status flag–is to be read first.

Since the AD7578 uses the successive approximation register (SAR) to hold conversion results (refer to Functional Diagram), it is necessary to wait until a conversion is finished before reading valid 12-bit data. Executing a READ instruction (HIGH or LOW byte) to the AD7578 while a conversion is in progress will place the existing contents of the SAR onto the data bus. Three different approaches can ensure valid 12-bit data is available for reading.

1. Insert a software delay greater than the ADC conversion time between the conversion start instruction and the data read instructions.
2. At user-defined intervals after a conversion start instruction, poll the internal converter status flag, BUSY. This signal is available on pin 8 during a HIGH byte READ instruction and is the most left-hand bit in a 16-bit right-justified word. The status bit can be shifted into a microprocessor's accumulator-carry position for testing (BUSY is HIGH during conversion).
3. Use the externally available $\overline{\text{BUSY}}$ (pin 20) signal as an interrupt to the microprocessor. This signal is LOW during a conversion and returns HIGH at conversion end.

Executing a WRITE instruction to the AD7578 while a conversion is in progress will restart the conversion.

COMPONENT SELECTION

1. Autozero Capacitor, C_{AZ}
   The autozero capacitor must be a low leakage, low dielectric absorption type such as polystyrene, polypropylene or teflon. To minimize noise connect the outside foil of C_{AZ} to AGND (pin 5), the analog system ground. C_{AZ} should be 2,200pF.
2. Clock Oscillator Components, R_{CLK}, C_{CLK1} and C_{CLK2}
   Clock pulses are generated by the action of series connected capacitors, C_{CLK1} and C_{CLK2} charging through an external resistor R_{CLK} and discharging through an internal switch. Nominal conversion time versus temperature for the recommended R_{CLK} and C_{CLK1}/C_{CLK2} combination is shown in Figure 10. Due to process variations, the actual operating frequency for this R_{CLK} and C_{CLK1}/C_{CLK2} combination can vary from device to device by up to 20%. For this reason, Analog Devices recommends using an external clock in the following situations:
   a. Applications requiring a conversion time which is within 20% of 100μs, the minimum conversion time for specified accuracy (a 140kHz clock frequency gives a 100μs conversion time).
   b. Applications which cannot accommodate conversion time differences which may occur due to unit clock frequency variations or temperature variations.

   It is possible to replace the fixed R_{CLK} resistor with a 50k potentiometer in series with a fixed 22kΩ resistor to allow individual adjustment of internal clock frequency in applications where 100μs conversion times are required. Reducing the value of R_{CLK} from 56k to 47k decreases the conversion time by typically 15μs.

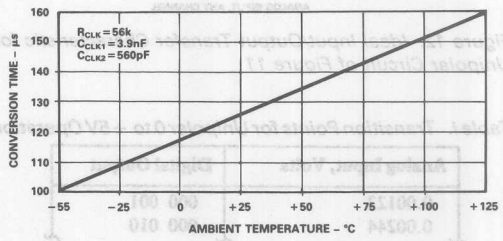

Figure 10. Typical Conversion Time vs. Temperature Using Internal Clock

APPLYING THE AD7578

The high input impedance of the analog input, AIN, allows simple analog interfacing. Zero to +5V signal sources can be connected directly to the analog input without additional buffering for source impedances up to 5kΩ (see Figure 11). The input/output transfer characteristic and transition points for this input signal range are shown in Figure 12 and Table I respectively. The designed transition points on the AD7578 transfer characteristic occur on integer multiples of 1LSB. The output code is Natural Binary with 1LSB = (F.S.) (1/4096) = (5/4096)V = 1.22mV.

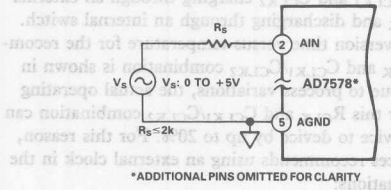

Figure 11. Unipolar 0 to +5V Operation

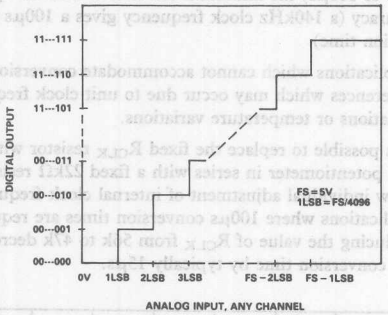

Figure 12. Ideal Input/Output Transfer Characteristic for Unipolar Circuit of Figure 11

Table I. Transition Points for Unipolar 0 to +5V Operation

Analog Input, Volts	Digital Output
0.00122	000 001
0.00244	000 010
2.49878	011 111
2.50000	100 000
2.50122	100 001
4.99756	111 110
4.99878	111 111

Signal ranges other than 0 to +5V are easily accommodated by using resistor divider networks to produce 0 to +5V signal ranges at the AD7578 input pins. Figure 13 shows a divider network to allow an input signal range of 0 to +10V. The input resistors must be selected to match within 0.01% and should be the same type and from the same manufacturer so that their temperature coefficients match. Note that since the source impedance has not been included in the resistor divider ratio, it must now be as low as possible. For Figure 13 with a source impedance of 0.5Ω the maximum error across the network is approximately 0.5LSB. The LSB size is (F.S.)(1/4096) = (10/4096)V = 2.44mV.

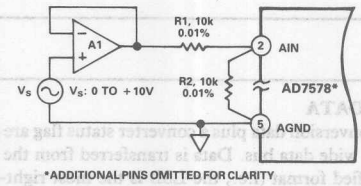

Figure 13. Unipolar 0 to +10V Operation

Bipolar signal ranges of −5V to +5V are accommodated by referencing the resistor divider network to V_{REF} as shown in Figure 14. With the resistor values shown, the signal source must be capable of sinking 0.5mA. The input/output transfer characteristic and transition points for this ±5V signal range are shown in Figure 15 and Table II respectively. The output code is Offset Binary with an LSB size of (F.S.)(1/4096) = (10/4096)V = 2.44mV.

With an analog input (V_S) of −1.22mV, the input offset voltage of A1 should be adjusted until the ADC output flickers between 0111 1111 1111 and 1000 0000 0000. Alternatively the −1/2LSB signal offset can be included in the signal conditioning electronics.

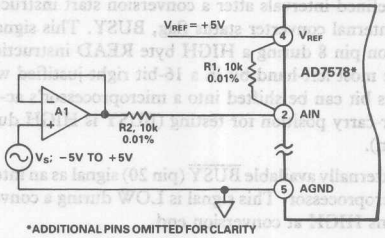

Figure 14. Bipolar −5V to +5V Operation

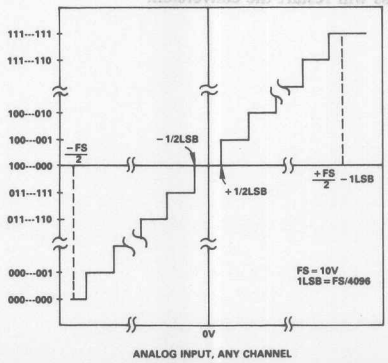

Figure 15. Ideal Input/Output Transfer Characteristic for Bipolar Circuit of Figure 14

Table II. Transition Points for Bipolar −5V to +5V Operation

Analog Input, Volts	Digital Output
−4.99878	000 001
−4.99634	000 010
−0.00122	100 000
+0.00122	100 001
+4.99389	111 110
+4.99634	111 111

Applications

Power Supply Decoupling: All power supplies to the AD7578 should be bypassed with either 10μF tantulum or electrolytic capacitors. To ensure good high frequency performance, each capacitor should be bypassed with an 0.01μF disc ceramic capacitor. All capacitors should be placed as close as possible to the AD7578.

Reference Circuit: Figure 16 shows how to configure an AD584LH to produce a reference voltage of 5.00V. R2 provides a typical adjustment range of ±75mV. The AD584LH will contribute less than 1LSB of gain error over the commercial temperature range.

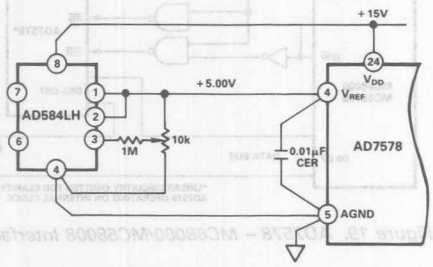

Figure 16. AD584LH as Reference Generator

Transient currents flow at the V_{REF} input during a conversion. To avoid dynamic errors place a 0.01μF disc ceramic capacitor from the V_{REF} pin to AGND.

Proper Layout: Layout for a printed circuit board should ensure that digital and analog signal lines are separated as much as possible. In particular, care should be taken not to run any digital track alongside an analog signal track or close to the autozero capacitor. The analog inputs, the reference input and the autozero input should be screened by AGND.

A single point analog ground separate from the logic system ground should be established at pin 5 (AGND) or as close as possible to the AD7578. This single point analog ground should be connected to the digital system ground, to which pin 6 (DGND) is connected, at one point only and as close to the AD7578 as possible. The autozero capacitor, bypass capacitors for the reference input and the analog supplies, AIN common and any input signal screening should be returned to the analog ground point. Low impedance analog and digital power supply common returns are essential to low noise operation of the ADC and the foil width for these tracks should be as wide as possible.

Noise: Input signal leads to AIN and signal return leads from AGND (pin 5) should be kept as short as possible to minimize input noise coupling. In applications where this is not possible, a shielded cable between source and ADC is recommended. Also since any potential difference in grounds between the signal source and ADC appears as an error voltage in series with the input signal, attention should be paid to reducing the ground circuit impedances as much as possible.

In applications where the AD7578 data outputs are connected to a continuously busy (and noisy) microprocessor bus it is possible to get LSB errors in conversion results. These errors are due to feedthrough from the microprocessor bus to the autozero comparator. The problem exists only for ceramic package versions of the AD7578, the electrically isolated metal lid acting like a conductor to distribute the digital noise around the package.

Grounding the lid to DGND eliminates this problem. Alternatively the AD7578 can be isolated from the microprocessor bus by means of three-state buffers.

Microprocessor Interfacing

MICROPROCESSOR INTERFACING

When the AD7578 is used with its own internal clock oscillator, microprocessor interfacing is straightforward and requires at most a few external gates (see Figures 17 through 19, 21 and 22). When the AD7578 is used with an external clock source, additional circuitry is required to extend the μP control signals (see Figure 20).

MC6800, MC6809 and 6502 MICROPROCESSORS

A typical interface to the AD7578 with any of the above microprocessors is shown in Figure 17. The decoder can be enabled high using VMA in 6800 systems or enabled low by NOR'ing ϕ_0 and ϕ_2 in 6502 systems or by NOR'ing E and Q in 6809 systems. Address line A2 of the 6800 has been tied to BYSL of the AD7578. Assuming the AD7578 is assigned a memory block starting at address 8000H, a write instruction to any address in this block will start a conversion. To read the conversion results, it is necessary only to bring control inputs $\overline{CS}$ and $\overline{RD}$ low. The BYSL input (tied to A2 of the μP) determines whether the data high or low byte is placed onto the 8-bit data bus. A read instruction to address 8000H will result in the low byte of data being transferred to the μP (BYSL = Low). Similarly a read instruction to any address having A2 HIGH and within the assigned memory block, e.g., 8004H, transfers the high byte of data to the μP. The converter status flag BUSY can be polled at intervals to check whether the present conversion has finished and valid 12-bit data is available. This is accomplished by the following instructions on the 6800:

```
LDA   A   $8004     Load Flag from AD7578
ASL   A             Shift Flag into Carry
BCC       FETCH     Branch to Data Fetch
                    Subroutine if BUSY is LOW
```

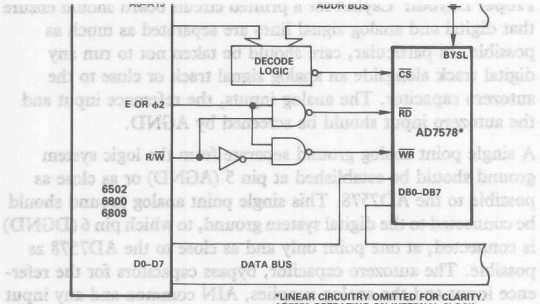

Figure 17. AD7578 – MC6800, 6809, 6502 Interface

8085A, Z80 MICROPROCESSORS

A typical interface to either of these microprocessors is shown in Figure 18. Not shown in the figure is the 8-bit latch required to demultiplex the 8085A common address/data bus. This interface uses slightly different low-level address decoding than the previous interface. Address line A0 of the µP has been tied to BYSL of the AD7578. This allows the 16-bit data move instructions on both the 8085A and the Z80 to be used when reading conversion results. Assuming the AD7578 is again assigned a memory block starting at address 8000H, a write instruction to any address in this block will start a conversion. The 12-bit conversion results can be read (low byte first then high byte) by a single read instruction;

On the 8085A

LHLD 8000

moves the conversion results into register pair HL

On the Z80

LD BC, (8000)

moves the conversion results into register pair BC

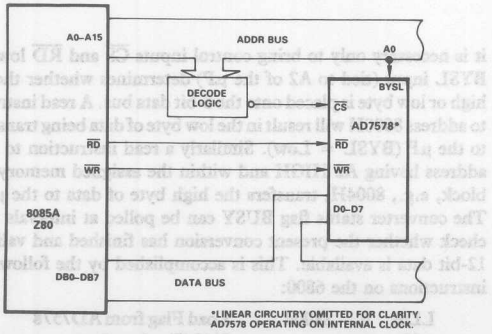

Figure 18. AD7578 – 8085A, Z80 Interface

MC68000, MC68008 MICROPROCESSOR

Figure 19 shows an AD7578–MC68000/MC68008 interface. Address line A1 of the µP has been connected to BYSL of the AD7578. With the simple decoding logic shown in Figure 19, the AD7578 is decoded in a memory block from C000H to FFFFH. A write instruction to any one of these addresses will start a conversion, i.e.,

starts a conversion. When the conversion is complete, the µP acquires the result by reading from the AD7578, i.e,

MOVEP. W $000 (A2), D0

This instruction places the conversion data in the D0 register of the µP. Address register A2 should contain an odd-order address (having A1 high) for the AD7578, e.g., $C003.

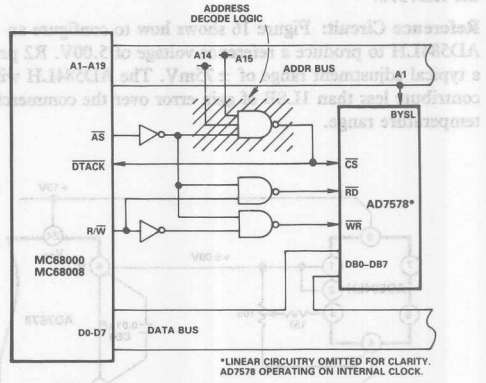

Figure 19. AD7578 – MC68000/MC68008 Interface

MICROPROCESSOR INTERFACE TO AD7578 WITH EXTERNAL CLOCK

Figure 20 shows the additional circuitry generally required to interface an 8-bit µP to the AD7578 operating from an external clock source. During a write operation, the 74121 monostable (one-shot) is triggered to latch the low level on the $\overline{CS}$ input into the 7477, a 4-bit bistable latch. The monostable timing components (not shown in Figure 20) should be chosen to provide an output pulse width corresponding to t_2 (EXT), the minimum autozero cycle time. To avoid any possibility of spurious triggering, the monostable should be enabled by a valid memory address signal. During a data read cycle, the 7477 latch is transparent and data is read normally. Note that the µP write and read cycle times are unaffected by the interface circuitry.

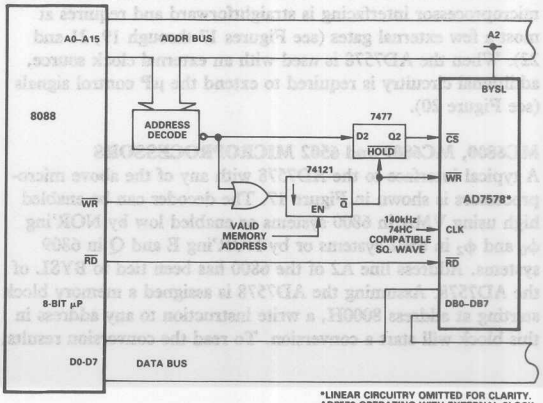

Figure 20. Interface to AD7578 Using External Clock

8088, 8086 MICROPROCESSORS

Figure 21 shows an AD7578–8088 interface.

Address line A0 of the μP is connected to BYSL of the AD7578. With the simple decoding shown in Figure 21 the AD7578 is decoded in a memory block from 4000H to 7FFFH.

A write instruction to any one of these addresses will start a conversion, i.e,

MOV 4004, AX

starts a conversion. When the conversion is finished the 8088 acquires the result by reading from the AD7578, i.e.,

MOV AX, 4000

places the conversion data in the accumulator.

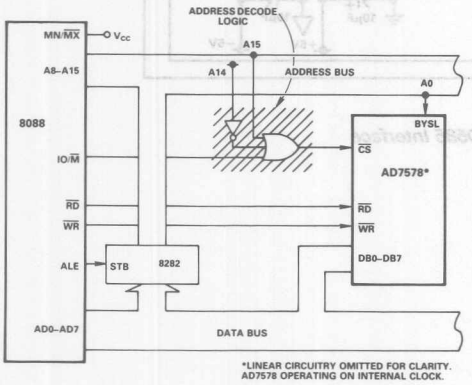

Figure 21. AD7578 – 8088 Interface

Figure 22 shows an AD7578–8086 interface. Address line A1 of the μP is connected to BYSL of the AD7578. The AD7578 is again decoded in a memory block from 4000H to 7FFFH.

A write instruction to any one of these addresses will start a conversion, i.e,

MOV 4008, AX

starts a conversion. When the conversion is finished, the 8086 acquires the result by reading from the AD7578 in two read cycles, i.e.,

MOV AL, 4000
MOV AH, 4002

places the conversion data in the accumulator.

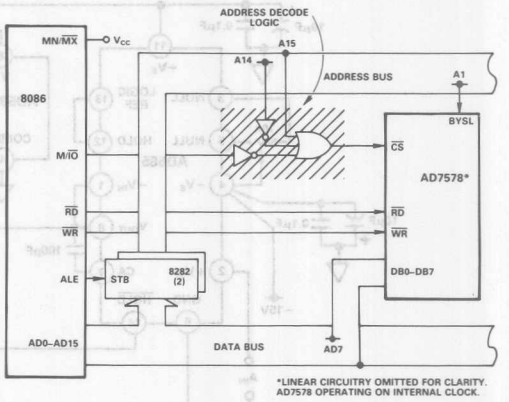

Figure 22. AD7578 – 8086 Interface

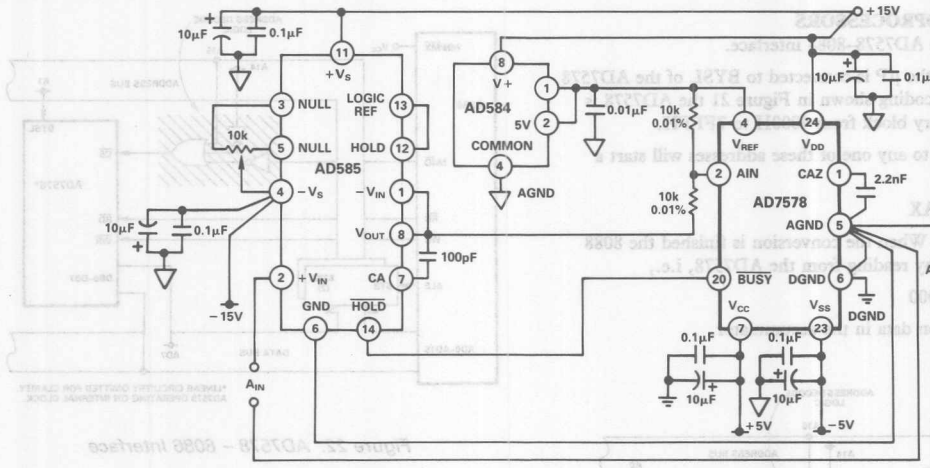
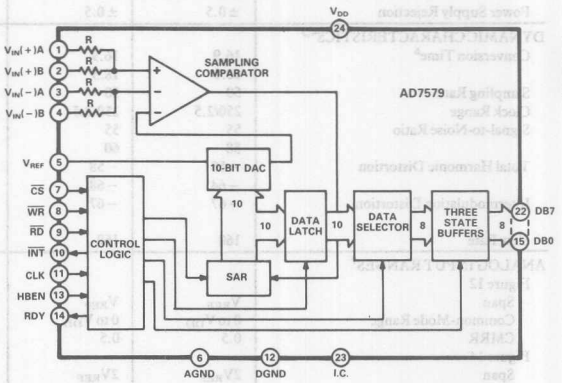
AD7578-AD585 SAMPLE-HOLD INTERFACE

Figure 23 shows an AD585 Sample-Hold Amplifier driving the analog input of the AD7578. At a sampling frequency of 8kHz the maximum input signal frequency is 4kHz. The AD7578 is configured for bipolar operation to allow an input signal swing of ±5V. No clock components are shown for the AD7578 but the conversion time should be adjusted for 100 microseconds. With an external hold capacitor of 100pF, the acquisition time for the sample-hold amplifier is 10 microseconds. The circuit operates from 0°C to +70°C.

To take a sample of the input, a WRITE instruction is executed to the AD7578 control inputs. The converter busy flag, $\overline{\text{BUSY}}$, is driven low indicating that a conversion is in progress. The falling edge of this $\overline{\text{BUSY}}$ signal places the sample-hold amplifier into the HOLD mode "freezing" the input signal to the AD7578. After 100 microseconds the conversion is finished and the $\overline{\text{BUSY}}$ signal is brought high. This allows a time of 25 microseconds for the AD585 to come out of the hold mode and acquire the input signal in time for the next sample. Between the end of one conversion and the start of the next, the conversion results must be read from the converter.

Careful circuit layout and power supply decoupling are necessary to obtain maximum performance from the system. Decoupling capacitors in the diagram are all 10μF electroytics in parallel with 0.01μF disc ceramics.





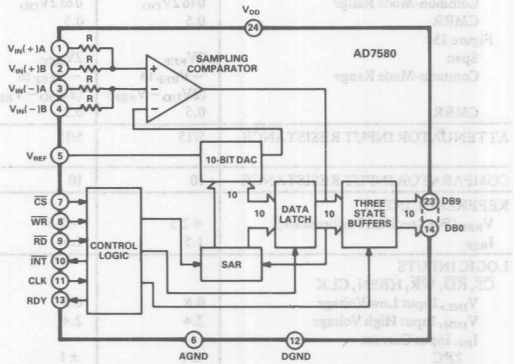


Figure 23. AD7578 – AD585 Interface

LC²MOS
10-Bit Sampling A/D Converters
AD7579/AD7580

FEATURES
- 20μs Conversion Time
- On-Chip Sample-Hold
- 50kHz Sampling Rate
- 25kHz Full-Power Input Bandwidth
- Choice of Data Formats
- Single +5V Supply
- Low Power (50mW)
- Skinny 24-Pin DIP and 28-Terminal Surface Mount Packages

FUNCTIONAL BLOCK DIAGRAMS

GENERAL DESCRIPTION

The AD7579 and AD7580 are 10-bit, successive approximation ADCs. They have differential analog inputs that will accept unipolar or bipolar input signals while operating from only a single +5V supply. Input ranges of 0 to +2.5V, 0 to +5V and ±2.5V are possible with no external signal conditioning. Only an external 2.5V reference and clock and control signals are required to make them operate.

With conversion time of less than 20μs and an on-chip sample-hold amplifier, the devices are ideally suited for digitizing ac signals. The maximum sampling rate is 50kHz, giving an input bandwidth of 25kHz. The parts are specified not only with traditional static specifications such as linearity and offset but also with dynamic specifications (SNR, Harmonic Distortion, IMD).

The AD7579 and AD7580 are microprocessor-compatible with standard microprocessor control inputs ($\overline{CS}$, $\overline{RD}$, $\overline{WR}$, RDY, $\overline{INT}$) and data outputs capable of interfacing to high-speed data buses. There is a choice of data formats, with the AD7579 offering an (8+2) read and the AD7580 offering a 10-bit parallel word.

Space saving and low power are also features of these devices. They dissipate less than 50mW from a single +5V supply and are offered in a 0.3″, 24-pin package and in plastic/ceramic chip carrier for surface mounting.

PRODUCT HIGHLIGHTS

1. 20μs conversion time with on-chip sample-hold makes the AD7579 and AD7580 ideal for audio and higher bandwidth signals, e.g., modem applications.
2. Differential analog inputs can accept unipolar or bipolar input signals, but only a single, +5V power supply is needed.
3. Versatile and easy-to-use digital interface has fast bus access/relinquish times, allowing connection to most popular microprocessors.

AD7579/AD7580—SPECIFICATIONS

(V_{DD} = +5V ± 5%, V_{REF} = +2.5V, AGND = DGND = 0V; f_{CLK} = 2.5MHz; All specifications T_{MIN} to T_{MAX} unless otherwise noted. Test conditions as in Figure 12 unless otherwise stated).

Parameter	J, A Versions	K, B Versions	S Version	Units	Conditions/Comments

NOTES
[1]Temperature Ranges as follows:
J, K Versions; 0 to +70°C
A, B Versions; −25°C to +85°C
S Version; −55°C to +125°C
[2]Zero code error and gain error adjusted to zero.
[3]Zero code error is measured with respect to an ideal first code transition which occurs at 1/2LSB.
[4]Sample tested at 25°C to ensure compliance.
[5]These specifications apply for full-scale input signals up to 20kHz.
[6]Accuracy may degrade at conversion times other than those specified.
[7]$V_{IN}(+)$ must always be equal to or more positive than $V_{IN}(-)$, in Figures 12, 14, 15.
Specifications subject to change without notice.

TIMING SPECIFICATIONS[1] (V_{DD} = +5V ±5%, V_{REF} = +2.5V, AGND = DGND = 0V)

Parameter[2,3,4]	Limit at 25°C (All Grades)	Limit at T_{min}, T_{max} (J, K, A, B Grades)	Limit at T_{min}, T_{max} (S Grade)	Units	Test Conditions/Comments
t_1	0	0	0	ns min	$\overline{CS}$ to $\overline{WR}$ Setup Time

t_{12}	110	135	150	ns max	Data Access Time After $\overline{RD}$
t_{13}	10	10	10	ns min	Data Hold Time, RDY Hold Time
	65	80	90	ns max	

NOTES
1. Timing specifications are sample tested at +25°C to ensure compliance. All input control signals are specified with $t_R = t_F$ = 20ns (10% to 90% of +5V) and timed from a voltage level of +1.6V.
2. t_4, t_{10}, t_{11} and t_{12} are measured with the load circuits of Figures 3 and 5 and defined as the time required for an output to cross 0.8V or 2.4V.
3. t_{13} is defined as the time required for the data lines to change 0.5V when loaded with the circuits of Figure 4.
4. $\overline{INT}$ and RDY are open-drain outputs and need 3kΩ external pull-up resistors for operation.

Specifications subject to change without notice.

*Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

TERMINOLOGY

LEAST SIGNIFICANT BIT (LSB)

An ADC with 10-bit resolution can resolve one part in 2^{10} (1/1024 of full scale). For the AD7579/AD7580 operating in the unipolar range with 2.5V span, one LSB is 2.44mV.

ZERO CODE ERROR

This is a measure of the difference between the ideal (0.5LSB) and the actual differential analog input level required to produce the first positive LSB code transition (00 . . . 00 to 00 . . . 01).

FULL-SCALE ERROR

The ideal difference between the first transition voltage and last transition voltage for an ADC is (F.S. − 2LSB). AD7579/AD7580 Full-Scale Error is defined as the deviation between this ideal difference and the measured difference.

COMMON-MODE RANGE

The voltage at both inputs to the AD7579/AD7580 can be raised above or lowered below analog ground potential, providing $V_{IN}(+)$ is equal to or more positive than $V_{IN}(-)$. Figures 12, 14, and 15 show circuits for various Analog Input Ranges. The Common-Mode Range represents the voltage extremes which can be applied to the circuits of Figure 12, 14 or 15. For example, when the AD7579/AD7580 is connected as in Figure 15, the Common-Mode Range is −2.5V to +7.5V.

SLEW RATE

Slew Rate is the maximum allowable rate of change of input signal such that the digital sample values are not in error. The Slew Rate performance of AD7579/AD7580 allows sampling of an input full-scale (2.5V pk-pk) sine wave up to 20kHz.

SIGNAL-TO-NOISE RATIO

Signal-to-Noise Ratio (SNR) is measured signal to noise at the output of the ADC. The signal is the rms magnitude of the fundamental. Noise is the rms sum of all nonfundamental signals up to half the sampling frequency. SNR is dependent on the number of quantization levels used in the digitization process; the more levels, the smaller the quantization noise. The theoretical SNR for a sine-wave input is given by:

$$SNR = (6.02N + 1.76)\ dB,$$

where N is the number of bits in the ADC. Thus for an ideal 10-bit ADC, SNR = 62dB.

INTERMODULATION DISTORTION

With inputs consisting of sine waves at two frequencies, fa and fb, any active device with nonlinearities will create distortion products, of order (m + n), at sum and difference frequencies of mfa ± nfb, where m,n = 0,1,2,3,----. Intermodulation terms are those for which m or n is not equal to zero.

HARMONIC DISTORTION

Harmonic distortion is the ratio of the square root of the sum-of-the-squares of the rms values of the harmonics to the rms value of the fundamental. For the AD7579/AD7580, Harmonic Distortion is:

$$20 \log \frac{\sqrt{(V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2)}}{V_1}\ dB,$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5, V_6 are the rms amplitudes of the individual harmonics.

PIN FUNCTION DESCRIPTION (DIP PACKAGE)

Mnemonic	Pin Number AD7579	Pin Number AD7580	Description
$V_{IN}(+)A$	1	1	Analog Input Pin.
$V_{IN}(+)B$	2	2	Analog Input Pin.
$V_{IN}(-)A$	3	3	Analog Input Pin.
$V_{IN}(-)B$	4	4	Analog Input Pin. The four analog input pins connect to the on-chip input attenuator (see Figure 6) and may be configured as in Table I for various input ranges.
V_{REF}	5	5	V_{REF} Input. This is nominally +2.5V.
AGND	6	6	Analog Ground
$\overline{CS}$	7	7	Chip Select Input.
$\overline{WR}$	8	8	Write Input. Used with $\overline{CS}$ to start conversion. See Tables II, III.
$\overline{RD}$	9	9	Read Input. Used with $\overline{CS}$ to read data. See Tables II, III.
$\overline{INT}$	10	10	Open Drain Output. High impedance during conversion. Goes low when conversion is complete.
CLK	11	11	Clock Input.
DGND	12	12	Digital Ground.
HBEN	13	–	High Byte Enable Input. Used in AD7579 for 2 Byte Reading. See Tables II, IV. Either the High Byte or the Low Byte may be read first.
RDY	14	13	Open Drain Output. This is accessed during Read Cycle. When accessed, it is low during conversion and high impedance when conversion is complete.
DB0-DB7	15-22	–	Three-State Data Outputs on AD7579. The data format is right justified.
DB0-DB9	–	14-23	Three-State Data Outputs on AD7580.
I.C.	23	–	Internal connection. This pin is connected internally on the AD7579. It should be left open and not used as a feed-through pin in double-sided printed circuit boards.
V_{DD}	24	24	Positive Power Supply. This is +5V nominal.

CIRCUIT INFORMATION

ANALOG INPUT CIRCUITRY

The AD7579 is a 10-bit ADC with an (8+2) output bus structure designed for 8-bit microprocessor systems. The AD7580 is a 10-bit ADC with a 10-bit parallel output bus structure. The ADC circuitry is identical in both parts. Block diagrams are shown on the first page of this data sheet.

Figure 6 shows the input circuitry to the ADC comparator. This comparator has differential inputs which are accessed through the attenuator networks made up of resistors R. The attenuators can be used to scale and offset analog input voltages, and this is done in Figures 14 and 15 to alter the basic ADC input range. The analog inputs to the comparator are differential with the provisos that V+ is always greater than or equal to V−, V− is greater than or equal to AGND and that V+ is less than or equal to V_{DD}. These conditions must be satisfied when using the ADC in any of the voltage ranges.

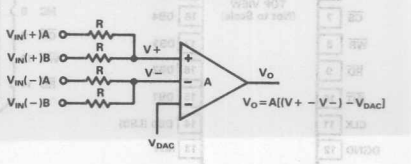

Figure 6. AD7579/AD7580 Input Circuit

Figure 7 shows an ac equivalent input circuit for the AD7579/AD7580 when used in the 2.5V Unipolar Mode of Figure 12. The ADC comparator is a sampled data comparator and the input circuitry for this is represented by S_A, Req and C_A. Req is a combination of the switch-on resistance and the input impedance of the comparator. When conversion starts, $V_{IN}(+)$ is sampled for at least ($2t_{CLK} + t_{WR} + 200ns$) before the comparator goes into the hold mode. This means that the analog input has a minimum of 1.1μs (f_{CLK} = 2.5MHz, t_{WR} = 100ns) to settle before the comparator makes a decision. By using the typical values in Figure 7 for R, Req and C_A, the input time constant is 50ns. Settling to ±1/4LSB in a 10-bit system takes 8.3 time constants or 415ns in this case. This means that $V_{IN}(+)$ has plenty of time to settle before the ADC comparison cycle begins. It is important to remember that any source resistance or source capacitance appearing at the input will also increase the settling time and this should be kept to a minimum in all cases.

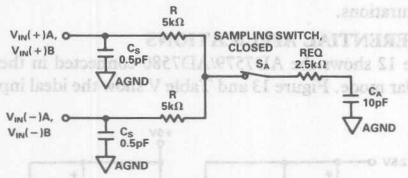

Figure 7. AD7579/AD7580 Equivalent Input Circuit During Sampling

With a 2.5MHz clock, the AD7579/AD7580 has a maximum conversion time of 18.5μs. If 1μs is allowed for reading the data outputs, the maximum sampling rate for the device is 50kHz. This means that the maximum analog input frequency is 25kHz according to the Nyquist theory. The ADC input impedance in the Unipolar Configuration of Figure 12 is 10MΩ. A medium bandwidth op amp will drive this at 25kHz. When the input attenuators are used for signal conditioning, the input impedance is 10kΩ. The drive requirements on the amplifier will now be greater but any errors resulting will be gain errors only. Suitable op amps for driving the AD7579/AD7580 in any of the input configurations are the AD711, AD OP-27, AD544. These will deliver specified device performance over the input bandwidth.

REFERENCE INPUT

The AD7579/AD7580 V_{REF} input is connected to the on-chip DAC. The input impedance of this is code dependent and the greatest variation occurs when the DAC resistors are at their lower limit. In this case, the impedance changes from 1.75kΩ to 5.25kΩ as the DAC is switched. To ensure that the error during conversion is less than 1/2LSB, the Reference output impedance should be less than 1Ω. References which satisfy this are the AD580 (shown in Figure 8) and the AD1403 from Analog Devices. If a trimmable reference such as the AD584 is used, it is possible to trim out the ADC full-scale error by adjusting the reference output.

INTERNAL SAMPLE-AND-HOLD

When an ADC without sample-and-hold is used to digitize ac signals, the analog input must not change by more than 1/2LSB during the conversion. This puts severe limitations on the allowable input signal bandwidth to such devices. A sample-and-hold amplifier must be used in front of the ADC if increased bandwidth is required. The charge balanced comparator used in the AD7579/AD7580 for the A/D conversion provides the user with an inherent sample-and-hold function. The ADC is specified to work with sampling rates up to 50kHz. This rate allows time to do a conversion and read the result into memory. Since at least two samples are needed to define an input sine wave according to the Nyquist theory, the analog input signal bandwidth for the AD7579/AD7580 is 25kHz. Figures 20, 21 and 22 show the performance of the ADC when digitizing ac signals.

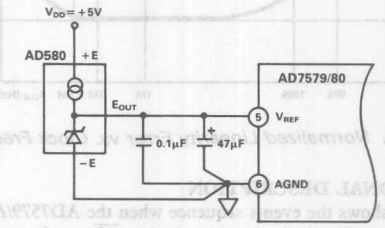

Figure 8. Using the AD580 as the Reference for the AD7579/AD7580

While the AD7579/AD7580 is converting, V+ (see Figure 6) is held and V− is being tracked. This limits the rate of change, $^{dv}/_{dt}$, on $V_{IN}(-)$. For example, if the Common-Mode frequency is 60Hz, then the allowable amplitude of this to introduce no more than 1/2LSB linearity error is 160mV pk-pk. As the Common-Mode frequency increases, this allowable amplitude decreases. Figure 9 shows how a 100mV pk-pk Common-Mode signal affects linearity error as its frequency is increased up to 1kHz.

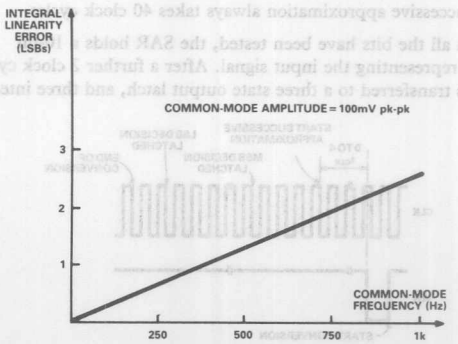

Figure 9. AD7579/AD7580 Error vs. Common-Mode Frequency

clock on the CLK input pin. This pin may be driven directly by CMOS or TTL buffers. The mark/space ratio on the clock can vary from 40/60 to 60/40. As the clock frequency is slowed down, it can result in slightly degraded accuracy performance. This is due to leakage effects on the hold capacitor in the internal sample-and-hold. Figure 10 is a typical plot of accuracy versus clock frequency for the ADC.

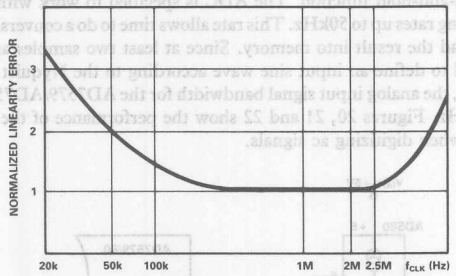

Figure 10. Normalized Linearity Error vs. Clock Frequency

FUNCTIONAL DESCRIPTION

Figure 11 shows the events sequence when the AD7579/AD7580 is converting. The device is selected when $\overline{CS}$ goes low and the first phase of conversion begins when $\overline{WR}$ goes low. This is an initializaton phase and causes the internal DAC to be set to full scale, comparators set to auto-zero and V+ (see Figure 6) to be sampled. The second phase begins some time after $\overline{WR}$ goes back high. This time can vary between 0 and 4 clock periods and depends on the state of an on-chip divide-by-4 counter which is used for internal synchronization. This is the start of the successive approximation procedure. V+ is held after 2-1/2 clock periods have elapsed. V− is sampled and the DAC output is switched into the comparator. There is $(1\text{-}1/2 \times t_{CLK})$ left for comparison and then the MSB result is latched. The MSB test takes 4 clock cycles as do each of the succeeding bit tests. Thus, the successive approximation always takes 40 clock cycles.

When all the bits have been tested, the SAR holds a 10-bit word representing the input signal. After a further 2 clock cycles this is transferred to a three state output latch, and three internal

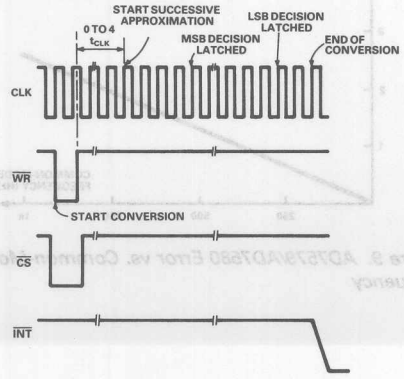

Figure 11. AD7579/AD7580 Conversion Sequence

both open drain outputs with RDY accessed by RD and INT being permanently available. When $\overline{INT}$ is loaded with the circuit of Figure 5(a), it typically takes 60ns to reach V_{OL}. $\overline{EOC}$ is only available on the AD7579 (see Table V). It appears on DB7, when reading the high Byte.

When the ADC is finished the conversion, the conditions of V+, V− and the comparators are maintained and the ADC is now ready to start a new conversion. If $\overline{WR}$ and CLK are asynchronous, the total time from start to end of conversion is variable. Minimum conversion time is $(t_{WR} + 42\ t_{CLK})$, and maximum conversion time is $(t_{WR} + 46\ t_{CLK})$.

APPLYING THE AD7579/AD7580

The AD7579/AD7580 has a flexible input stage consisting of two input attenuators. It is possible to realize various analog input ranges by reconfiguring these attenuators. The following diagrams show the ADC connected in the most popular configurations.

DIFFERENTIAL APPLICATIONS

Figure 12 shows the AD7579/AD7580 connected in the standard unipolar mode. Figure 13 and Table V show the ideal input/output

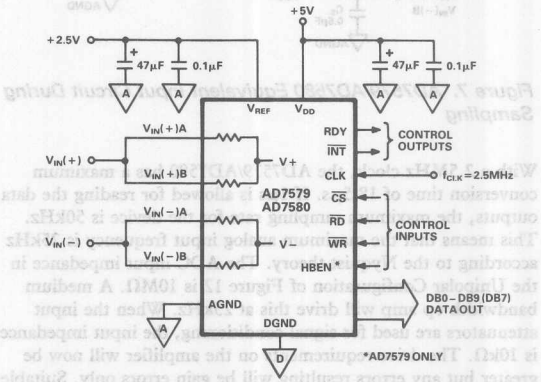

Figure 12. Unipolar 2.5V Operational Diagram

Table V. Input/Output Code Table for Figure 12

transfer characteristic and the input/output code table respectively. Code transitions occur between successive integer LSB values (i.e., 1/2LSB, 3/2LSBs, etc.). The output code is straight binary with 1LSB = FS/1024 = 2.5/1024V = 2.4mV. The input voltage span is 2.5V and the common-mode range is 0V to +5V, when V_{DD} = 5V. This means that the lowest voltage which can be tolerated at any of the analog inputs is 0V, and the highest voltage which can be tolerated is +5V.

Figures 14 and 15 show the input attenuators on the AD7579/AD7580 configured to change the basic range of the device. A 5V range can be configured by grounding one end of each attenuator and applying the differential input to the other ends. This is shown in Figure 14. The span is 5V and the common-mode range is 0 to +10V. In Figure 15, one end of each attenuator is tied to V_{REF} (2.5V), and this allows each of the other legs to go to −2.5V without causing the comparator input to go negative. Assuming V_{REF} is 2.5V, the span of this circuit is 5V and the common-mode range is −2.5V to +7.5V. Note that reducing V_{DD} below 5 volts causes a corresponding reduction in CMR. See Specifications page for full details.

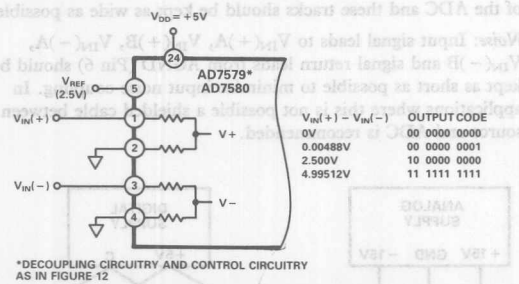

Figure 14. 5V Span with 0 to 10V CMR

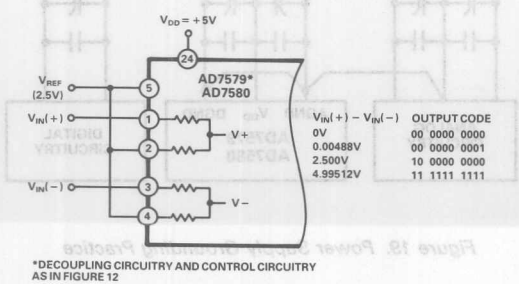

Figure 15. 5V Span with −2.5V to +7.5V CMR

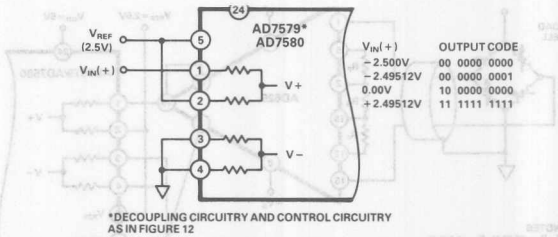

Figure 16. Single-Ended Bipolar Operation, −2.5V to +2.5V

SINGLE-ENDED APPLICATIONS

In many cases, users of the AD7579/AD7580 will want to measure single-ended input voltages (i.e., ground referred signals). The circuits of Figures 12, 14 and 15 can be easily adapted to accept such signals. If $V_{IN}(-)$ in Figure 12 is tied to AGND, then the analog input range is 0V to +2.5V. By connecting $V_{IN}(-)$ of Figure 14 to AGND, the analog input range becomes 0V to +5V. Figure 15 can be modified as in Figure 16 to accept input voltages in the range −2.5V to +2.5V. Each of these circuits are special cases of the Differential Input circuits and are achieved by making the negative input to the internal comparator equal to AGND.

OFFSET AND FULL-SCALE ADJUSTMENT

Figure 17 shows the AD7579/AD7580 connected in the single-ended Unipolar 2.5V range with offset and full-scale calibration circuitry. The zero error of the ADC is the deviation of the actual LSB transition from the ideal LSB transition. In many cases, the zero of the ADC will not need adjustment. When it does, R1 in Figure 17 provides 25mV of adjustment which is sufficient to null out both the op amp and ADC offset error. Resistors R3 and R4 bias $V_{IN}(-)$ to approximately 8mV and ensure that the offset error is never positive. This allows the error to be nulled in the single supply system of Figure 17. Apply +0.5LSB to V_{IN} and adjust R1 until the ADC output code flickers between 00 ..... 000 and 00 ..... 001.

For full-scale calibration, apply a voltage of (2.5V − 1.5LSB) to V_{IN}. Then adjust R2 until the output code flickers between 11 ..... 110 and 11 ..... 111. When the full-scale calibration is complete, return to the offset adjustment procedure and check that further adjustment is not necessary.

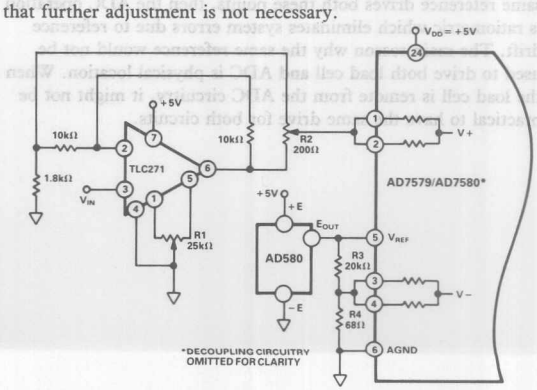

Figure 17. Offset and Full-Scale Calibration for Single-Ended Circuit

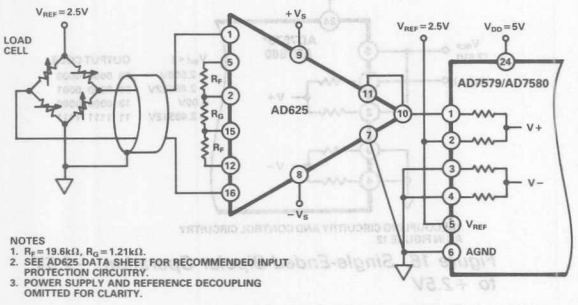

Figure 18a. AD7579/AD7580 and AD625 in a Data Acquisition System

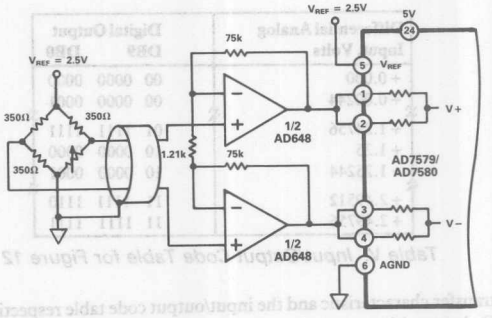

Figure 18b. AD7579/AD7580 and AD648 in a Data Acquisition System

AD7579/AD7580 IN DATA ACQUISITION SYSTEMS

The AD7579/AD7580 is suitable for many data acquisition circuits. Figure 18a shows one such circuit in which a load cell is used to produce a signal in response to an applied force. Typically these transducers produce 30mV full scale per volt of excitation. Since the excitation in this case is 2.5V, the output from the load cell is ±75mV when the maximum specified force is applied. The AD625 Instrumentation Amplifier is set for a gain of 33.33 which means that the input signal to the ADC is ±2.5V. Thus, the AD7579/AD7580 is configured in the single-ended, ±2.5V range of Figure 16. When no force is applied to the load cell, the ADC output will sit at mid-scale. With maximum negative force applied the ADC output will be all zeros; whereas, with maximum positive force the output will be all 1s. Offset and gain calibration of this system can be accomplished by trimming the offsets and gain of the instrumentation amplifier.

Figure 18b shows a differential transducer unbalanced by ≈10Ω supplying a 0 to 20mV maximum signal. The resistors are chosen for a gain of 125, and the ADC is configured to accept 0 to 2.5V differential signal. This is a lower-cost alternative to using an instrumentation amplifier.

Note that in the circuits of Figure 18, V_{REF} for the ADC and the excitation voltage for the load cell are both +2.5V. If the same reference drives both these points, then the ADC operation is ratiometric which eliminates system errors due to reference drift. The main reason why the same reference would not be used to drive both load cell and ADC is physical location. When the load cell is remote from the ADC circuitry, it might not be practical to have the same drive for both circuits.

APPLICATIONS HINTS

Layout: To obtain the best performance from the AD7579/AD7580, lay it out on a printed circuit board. Digital and analog lines on the board should be separated as much as possible. In particular, take care not to run any digital track adjacent to an analog signal track or underneath the AD7579/AD7580. The analog inputs should be screened by AGND.

Grounding: Establish a single-point analog ground (STAR ground) at Pin 6 (AGND) or as close as possible to the AD7579/AD7580. This is shown in Figure 19. Pin 12 (AD7579/AD7580 DGND) and all other analog grounds should be connected to this single analog ground point. However, do not connect any other digital grounds to this analog ground point. Low impedance analog and digital power supply returns are essential to low noise operation of the ADC and these tracks should be kept as wide as possible.

Noise: Input signal leads to $V_{IN}(+)A$, $V_{IN}(+)B$, $V_{IN}(-)A$, $V_{IN}(-)B$ and signal return leads from AGND (Pin 6) should be kept as short as possible to minimize input noise coupling. In applications where this is not possible a shielded cable between source and ADC is recommended.

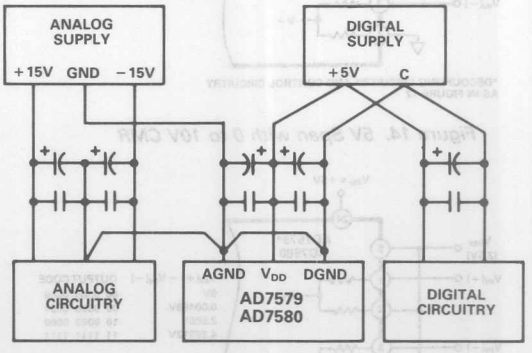

Figure 19. Power Supply Grounding Practice

DIGITAL SIGNAL PROCESSING APPLICATIONS

In Digital Signal Processing (DSP) application areas like voice recognition, echo cancellation and adaptive filtering, the dynamic characteristics (SNR, Harmonic Distortion, Intermodulation Distortion) of ADCs are critical. For this reason, the AD7579/AD7580 is specified dynamically as well as with standard D.C. specifications (linearity error, offset error, etc.).

Figure 20 shows a 2048 point FFT plot of an AD7579/AD7580 with an input signal of 3.58kHz. The SNR is 60.1dBs. The largest harmonic appears at $2f_O$ (7.16kHz) and is 70dB down from the fundamental. Harmonics above $3f_O$ are in the noise floor. Note that when SNR is calculated, it includes harmonics.

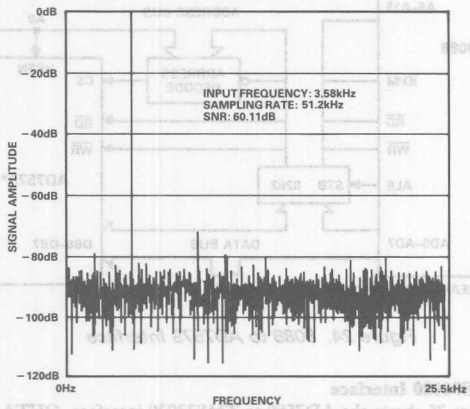

Figure 20. AD7579/AD7580 Spectral Response

If these were excluded the SNR figure would be closer to the ideal of 62dB for a 10-bit ADC. The relationship between Signal-to-Noise Ratio (SNR) and ADC resolution is expressed in the following equation:

$$SNR = (6.02N + 1.76)dB$$

This is for an ideal ADC with no differential or integral linearity errors. These errors will cause a degradation in SNR. By working backwards in the above equation it is possible to get a measure of ADC performance expressed in effective number of bits. This is shown over frequency in Figure 21 for the AD7579/AD7580. The effective number of bits typically falls between 9.7 and 9.8 corresponding to SNRs of 60.0 and 60.6dBs.

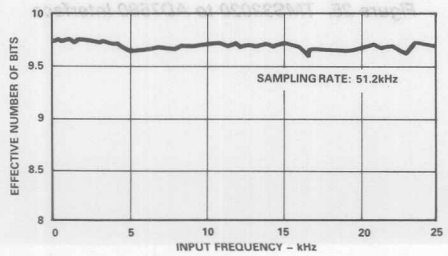

Figure 21. AD7579/AD7580 Effective Number of Bits

When a sine wave of specified frequency is applied to the AD7579/AD7580 and several thousand samples are taken, it is possible to plot a histogram showing the frequency of occurrence of each of 1024 ADC codes. A perfect ADC would produce a cusp probability density function described by the equation

$$p(V) = \frac{1}{(A^2 - V^2)^{1/2}}$$

A is the peak amplitude of the sine wave and p(V) the probability of occurrence at the voltage V. If a particular step is wider than the ideal width, then the code associated with that step will accumulate more counts than the code for an ideal step. Likewise, a step narrower than ideal width will have fewer counts. Missing codes are easily seen because a missing code means zero counts for a particular code. The absence of large spikes in the histogram indicates small differential nonlinearity. The actual histogram obtained is shown in Figure 22 and corresponds very well with the ideal cusp shape. It shows that the AD7579/AD7580 has very small differential nonlinearity and no missing codes with an input frequency of 25kHz.

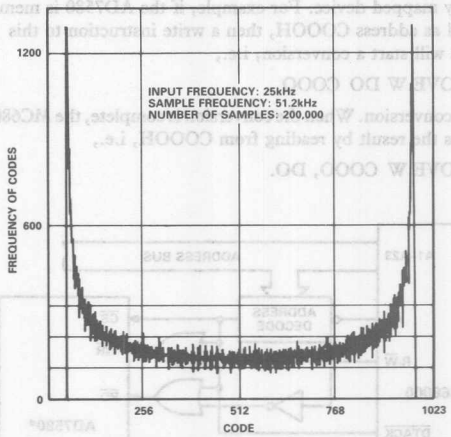

Figure 22. Histogram Plot for AD7579/AD7580

Whenever the AD7579/AD7580 is used to sample ac signals, it is essential that the signal sampling occurs at exactly equal intervals. This minimizes errors due to sampling uncertainty or jitter. The $\overline{WR}$ command for the AD7579/AD7580 needs to be synchronized with the CLK input to ensure equal interval sampling.

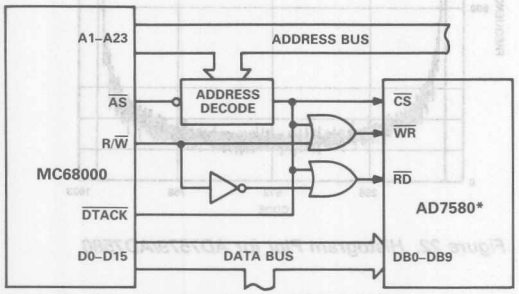
Two conditions must be satisfied to ensure proper synchronization: 1) The time interval between successive $\overline{WR}$ signals needs to be long enough to allow a conversion to finish and the data to be read into memory. 2) Because of the internal operation of the ADC, the number of clock pulses between successive write signals must be a multiple of four.

The conversion time for the AD7579/AD7580 has a maximum value of (t_{WR} + 46 t_{CLK}). If 4 t_{CLK} is allowed for reading the data outputs into a buffer then the interval between successive $\overline{WR}$ signals must be at least 50 t_{CLK}. The easiest way to satisfy both this requirement and number 2 above is to divide f_{CLK} by 64 to produce the $\overline{WR}$ signal. Alternatively, if a programmable timer/counter on a processor board is available, then it will be possible to easily divide f_{CLK} by 52.

Reading Data

Conversion is started in the AD7579/AD7580 by bringing $\overline{WR}$ low. It is recommended that the user wait until conversion is complete before reading data. This can be achieved in any of the following ways:

1. Insert a software delay greater than the ADC conversion time between the conversion start instruction and the data read instructions.
2. Use the externally available $\overline{INT}$ signal to interrupt the microprocessor. This is an open drain output which goes low at the end of conversion.
3. On the AD7579, it is possible to interrogate the $\overline{EOC}$ status flag (See Table IV) to determine when conversion is complete. Reading may then proceed.



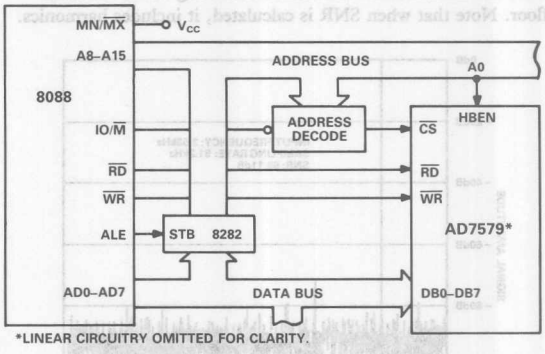
MC68000 Interface

Figure 23 shows an interface diagram for the AD7580 and the MC68000. The address decoding means that the AD7580 is a memory mapped device. For example, if the AD7580 is memory mapped as address COOOH, then a write instruction to this address will start a conversion, i.e.,

MOVE.W DO COOO

starts a conversion. When the conversion is complete, the MC68000 acquires the result by reading from COOOH, i.e.,

MOVE.W COOO, DO.

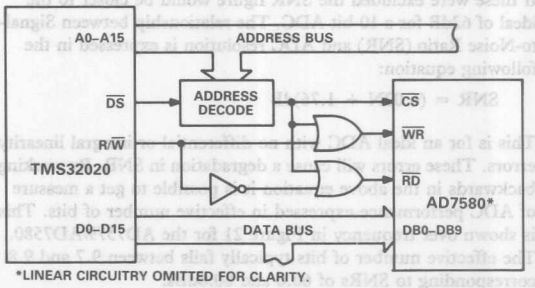


*LINEAR CIRCUITRY OMITTED FOR CLARITY.

Figure 23. MC68000 to AD7580 Interface

The AD7579, with its (8 + 2) data format, is ideal for use with the 8088 microprocessor. Figure 24 is the interface diagram. Again, a write instruction is required to start a conversion and a read at the end of conversion reads data into the processor. For the 8088 the appropriate instructions are:

MOV COOO, AX	Start a conversion
MOV AX, COO1	Read 2 MSBs of data
MOV AX, COOO	Read 8 LSBs of data



*LINEAR CIRCUITRY OMITTED FOR CLARITY.

PRINTED CIRCUIT BOARD LAYOUT

Figure 26 is a circuit diagram showing the AD7579 or AD7580 being used to digitize an analog signal. The circuit board contains the ADC, reference, and a grid where the user can add additional circuitry. If the AD7580 is used, then links L6 and L8 should be inserted; and if AD7579 is used, L7 should be inserted with L6 and L8 omitted. Note that Pins 13 to 23 are not labelled. Depending on which ADC is used the function of these pins changes. See the Pin Function Description section for full details.

Links L1 to L5 at the analog input allow the user to choose various analog input ranges. With L1, L2 and L3 in place and the others omitted, the input range is 0V to +2.5V. Omitting L3 allows the user to measure input voltages which have a common-mode signal. The 0V to +5V range is achieved by inserting L2, L3 and L4 and omitting L1 and L5. With L2, L3 and L5 in place and L1, L4 omitted, the Analog input range is −2.5V to +2.5V.

IC2 (AD580) provides the +2.5V reference for the ADC. All the input and output control signals enter and leave the board through J1, which can be a Eurocard connector or a standard edge connector. Resistors R1 and R2 are the pull-ups required for the RDY and $\overline{INT}$ open-drain outputs. Note that the complete circuit operates from a +5V power supply.

The printed circuit board layout is shown in Figures 27 and 28. Figure 27 is the component side layout and Figure 28 is the solder side layout. The component overlay is shown in Figure 29.

In the layout, the AD580 is kept as close to the AD7579/AD7580 as possible. The STAR ground point is located at Pin 6 (AGND) of the ADC. Pin 12 (DGND), reference ground and the analog ground plane are connected to this point.

To ensure optimum performance, the AD7579/AD7580 power supply is decoupled with C1 and C2. The V_{REF} input to the ADC is decoupled with C3 and C4. Note how all the decoupling capacitors are placed as close as possible to the ADC.

8-Bit, 8-Channel DAS

AD7581

FEATURES

- 8-Bit Resolution
- On-Chip 8 X 8 Dual-Port Memory
- No Missed Codes Over Full Temperature Range
- Interfaces Directly to Z80/8085/6800
- CMOS, TTL Compatible Digital Inputs
- Three-State Data Drivers
- Ratiometric Capability
- Interleaved DMA Operation
- Fast Conversion
- A/D Process Totally Transparent to μP
- Low Cost

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7581 is a microprocessor compatible 8 bit, 8 channel, memory buffered, data-acquisition system on a monolithic CMOS chip. It consists of an 8 bit successive approximation A/D converter, an 8 channel multiplexer, 8 X 8 dual-port RAM, three-state DATA drivers (for interface), address latches and microprocessor compatible control logic. The device interfaces directly to 8080, 8085, Z80, 6800 and other microprocessor systems.

The successive approximation conversion takes place on a continuous, channel sequencing, basis using microprocessor control signals for the clock. Data is automatically transferred to its proper location in the 8 X 8 dual-port RAM at the end of each conversion. When under microprocessor control, a READ DATA operation is allowed at any time for any channel since on-chip logic provides interleaved DMA. The facility to latch the address inputs ($A_0 - A_2$) with ALE enables the AD7581 to interface with μP systems which feature either shared or separate address and data buses.

GENERAL CIRCUIT INFORMATION

BASIC CIRCUIT DESCRIPTION

The AD7581 accepts eight analog inputs and sequentially converts each input into an eight-bit binary word using the successive approximation technique. The conversion results are stored in an 8 X 8 bit dual-port RAM. The device runs either directly from the microprocessor clock (in 6800 type systems) or from some suitable signal (e.g. ALE in 8085 type systems). Most applications require only a –10V reference and a +5V supply. Start-up logic is included on the device to establish the correct sequences on power-up. A maximum of 800 clock pulses are required for this period. Figure 1 shows the AD7581 functional diagram.

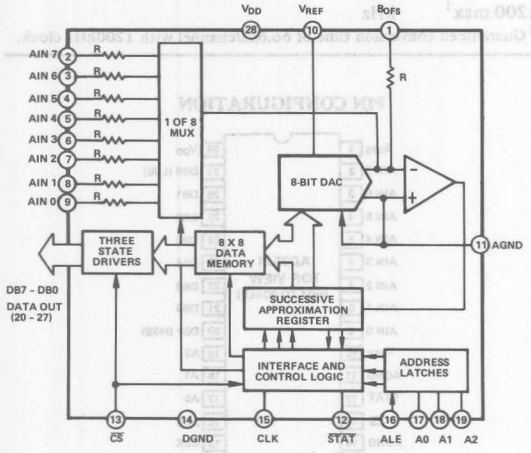

Figure 1. AD7581 Functional Diagram

Conversion of a single channel requires 80 input clock periods and a complete scan through all channels requires 640 input clock periods. When a channel conversion is complete, the successive approximation register contents are loaded into the proper channel location of the 8 X 8 RAM. At this time a status signal output, $\overline{STAT}$ (pin 12), gives a short negative going pulse (8 clock periods). This negative going $\overline{STAT}$ pulse is extended to 72 clock periods when channel 1 conversion is complete. An external pulse-width detector connected to the status pin can be used to derive conversion-related timing signals for microprocessor interrupts (see Channel Identification opposite page). Simultaneous with $\overline{STAT}$ going low, the MUX address is decremented. Eight clock periods later the next conversion is started.

Automatic interleaved DMA is provided by on-chip logic to ensure that memory updates take place at instants when the microprocessor is not addressing memory. Memory locations are addressed by A_0, A_1 and A_2. This address may be latched by ALE for systems which feature a multiplexed address/data bus or alternatively, for systems which have separate address and data buses, the address latches can be made transparent by tying ALE (pin 16) HIGH. $\overline{CS}$ (pin 13) activates three-state buffers to place addressed data on the $DB_0 - DB_7$ data output pins.

A/D CIRCUIT DETAILS

In the successive approximation technique, successive bits, starting with the most significant bit (DB_7), are applied to the input of the D/A converter. The DAC output is then compared to the unknown analog input voltage, A_{IN} (n), using a comparator. If the DAC output is greater than $A_{IN}(n)$, the data latch for the trial bit is reset to zero, and the next smaller data bit is tried. If the DAC output is less than $A_{IN}(n)$, the trial data bit stays in the "1" state, and the next smaller data bit is tried. Each successive bit is tried, compared to $A_{IN}(n)$, and set or reset in this manner until the least significant bit (DB_0) decision is made. The successive approximation register now contains a valid digital representation of $A_{IN}(n)$. $A_{IN}(n)$ is assumed to be stable during conversion.

The current weighting D/A converter is a precision multiplying DAC. Figure 2 shows the functional diagram of the DAC as used in the AD7581. It consists of a precision Silicon Chromium thin film R/2R ladder network and 8 N-channel MOSFET switches operated in single-pole-double-throw.

The currents in each 2R shunt arm are binarily weighted i.e., the current in the MSB arm is V_{REF} divided by 2R, in the second arm is V_{REF} divided by 4R, etc. Depending on the D/A logic input (A/D output) from the successive approximation register, the current in the individual shunt arms is steered either to A_{GND} or to the comparator summing point.

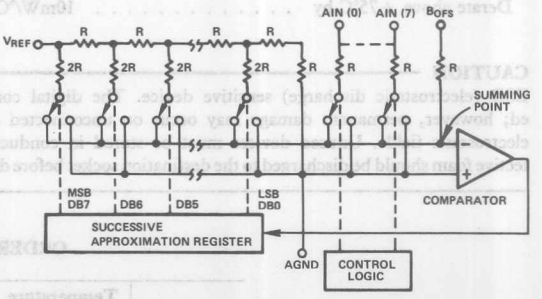

Figure 2. D/A Converter as Used in AD7581

TIMING AND CONTROL OF THE AD7581

CHANNEL SELECTION

Table I shows the truth table for the address inputs. The input address is latched when ALE goes LOW. When ALE is HIGH the address input latch is transparent.

A2	A1	A0	ALE	Channel Data To Be Read
0	0	0	1	Channel 0
0	0	1	1	Channel 1
0	1	0	1	Channel 2
0	1	1	1	Channel 3
1	0	0	1	Channel 4
1	0	1	1	Channel 5
1	1	0	1	Channel 6
1	1	1	1	Channel 7

Table I. Channel Selection Truth Table

TIMING AND CONTROL

A typical timing diagram is shown in Figure 3. When $\overline{CS}$ is HIGH, the three-state data drivers are in the high-impedance state. When $\overline{CS}$ goes LOW the data drivers switch to the low-impedance state (i.e., low impedance to DGND or to V_{DD}). Output data is valid after time t_{ACC}.

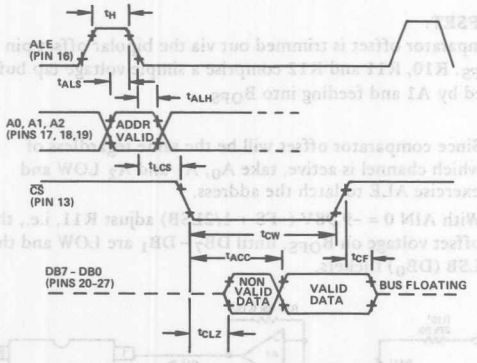

Figure 3. Timing Diagram for the AD7581

SWITCHING TERMINOLOGY

t_H: ALE pulse width requirement.
t_{ALH}: Address Valid to latch hold time.
t_{ALS}: Address Valid to latch set-up time.
t_{LCS}: Address latch to Chip Select set-up time.
t_{CW}: Chip Select pulse width requirement.
t_{ACC}: Chip Select to valid data propagation delay.
t_{CF}: Chip Select to output data float propagation delay.
t_{CLZ}: Chip Select to low impedance data bus.

CHANNEL IDENTIFICATION

In some real-time applications, it may be necessary to provide an interrupt signal when a particular channel receives updated data. To achieve this, it is necessary to identify which channel is currently under conversion. The $\overline{STAT}$ output provides an identifying signal by staying low for an additional 64 clock periods over normal (8 clock periods) when channel 0 is active. This is illustrated in Figure 4. Memory update takes place on a rising edge of a clock pulse and is completed in 200ns. This occurs 6 clock periods before $\overline{STAT}$ goes low.

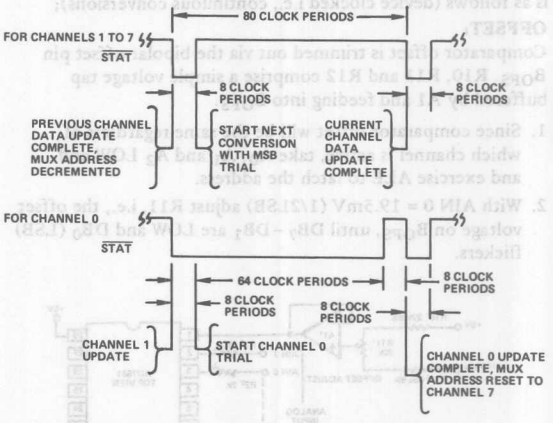

Figure 4. $\overline{STAT}$ Output for Channel Identification

One simple circuit using the $\overline{STAT}$ output is shown in Figure 5. The time constant RC is chosen such that X_2 ignores the normal $\overline{STAT}$ low pulse width (8 clock periods wide) but respond to the much wider $\overline{STAT}$ low pulse width (72 clock periods wide) occurring during channel 0 conversion. Typically for a 1μs clock period C = 0.022μF, R = 1.8kΩ.

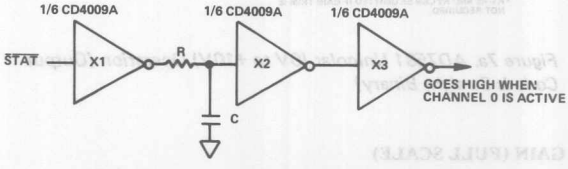

Figure 5. Hardware Channel Identification

Another possibility is to use the microprocessor to interrogate the $\overline{STAT}$ output and hence determine channel identity. A simple routine is shown in Figure 6.

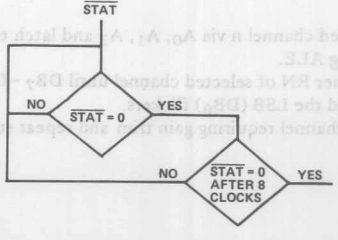

Figure 6. Software Channel Identification

UNIPOLAR BINARY OPERATION

Figures 7a and 7b show the analog circuit connections and typical transfer characteristic for unipolar operation (0V to +10V). An AD584 is used for the -10V reference. Calibration is as follows (device clocked i.e., continuous conversions);

OFFSET:

Comparator offset is trimmed out via the bipolar offset pin B_{OFS}. R10, R11 and R12 comprise a simple voltage tap buffered by A1 and feeding into B_{OFS}.

1. Since comparator offset will be the same regardless of which channel is active, take A_0, A_1 and A_2 LOW and and exercise ALE to latch the address.
2. With AIN 0 = 19.5mV (1/2LSB) adjust R11, i.e., the offset voltage on B_{OFS}, until $DB_7 - DB_1$ are LOW and DB_0 (LSB) flickers.

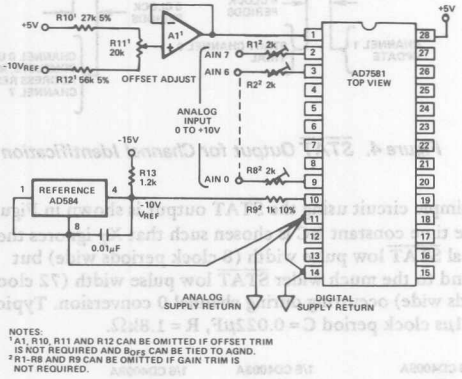

Figure 7a. AD7581 Unipolar (0V to +10V) Operation (Output Code is Straight Binary)

GAIN (FULL SCALE)

In many applications gain adjustment is not required thus removing the need for trimmers in the analog channels. For channels requiring gain trim, the following procedure is recommended. Offset adjustment must be performed before gain adjustment.

1. Apply +9.941V (FS - 3/2LSB) to all input channels AIN (0-7).
2. Select required channel n via A_0, A_1, A_2 and latch the Address using ALE.
3. Adjust trimmer RN of selected channel until $DB_7 - DB_1$ are HIGH and the LSB (DB_0) flickers.
4. Select next channel requiring gain trim and repeat steps 2 and 3.

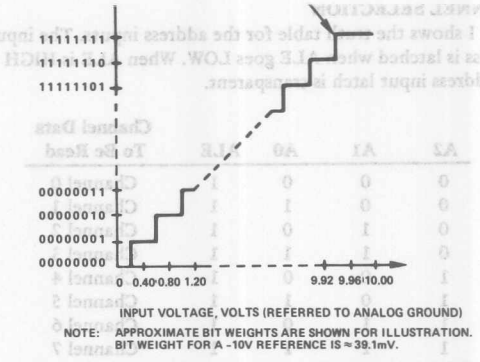

Figure 7b. Transfer Characteristic for Unipolar Circuit of Figure 7a

UNIPOLAR (COMPLEMENTARY BINARY) OPERATION

Figures 8a and 8b show the analog circuit connections and typical transfer characteristic for unipolar (complementary binary) operation.
Calibration is as follows (continuous conversions);

OFFSET:

Comparator offset is trimmed out via the bipolar offset pin B_{OFS}. R10, R11 and R12 comprise a simple voltage tap buffered by A1 and feeding into B_{OFS}.

1. Since comparator offset will be the same regardless of which channel is active, take A_0, A_1 and A_2 LOW and exercise ALE to latch the address.
2. With AIN 0 = -9.98V (-FS + 1/2LSB) adjust R11, i.e., the offset voltage on B_{OFS}, until $DB_7 - DB_1$ are LOW and the LSB (DB_0) flickers.

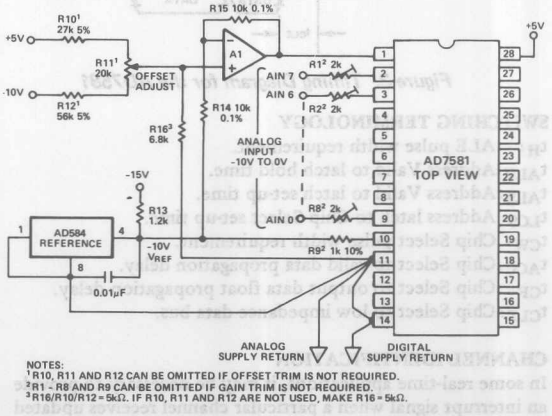

Figure 8a. AD7581 (0V to -10V) Operation (Output Code is Complementary Binary)

In many applications gain adjustment is not required thus removing the need for trimmers in the analog channels. For channels requiring gain trim, the following procedure is recommended. Offset adjustment must be performed before gain adjustment.

1) Apply -58.6mV (3/2LSB) to all input channels AIN (0-7).
2) Select required channel n via A_0, A_1, A_2 and exercise ALE to latch the address.
3) Adjust trimmer RN of selected channel until DB_7 - DB1 are HIGH and the LSB (DB_0) flickers.
4) Select next channel requiring gain trim and repeat step 2 and 3.

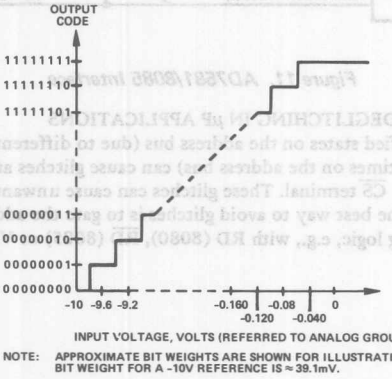

Figure 8b. Transfer Characteristic for Unipolar Circuit of Figure 8a

BIPOLAR (OFFSET BINARY) OPERATION

Figures 9a and 9b illustrate the analog circuitry and transfer characteristic for ±5V bipolar operation. Output coding is offset binary. Comparator offset correction is again applied to the B_{OFS} pin.

Calibration is as follows (continuous conversions);

OFFSET:

1. Apply -4.980V (-FS/2 + 1/2LSB) to all input channels AIN (0-7).
2. Trim R11 of the comparator offset circuit until DB_7 - DB_1 are LOW and the LSB (DB_0) flickers.

GAIN (FULL SCALE)

1. Apply +4.941V (+FS/2 -3/2LSB) to all input channels, A_{IN} (0-7).
2. Select required channel n via A_0, A_1, A_2, and latch the address using ALE.
3. Adjust trimmer RN of selected channel until DB_7 - DB_1 are HIGH and the LSB (DB_0) flickers.

2 and 3.

5. Apply -19.5mV to each gain-trimmed channel. If the ADC output code does not flicker between 01111111 and 10000000 repeat the calibration procedure.

INTERFACING THE AD7581

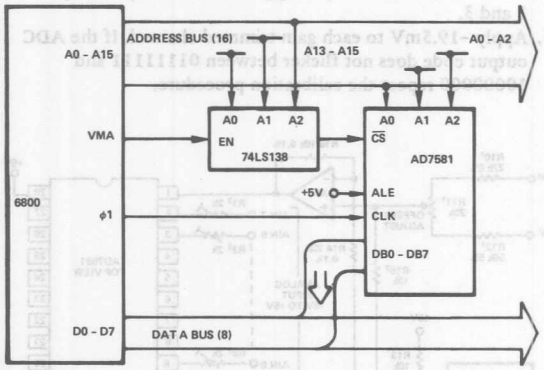

Figure 10. AD7581/6800 Interface

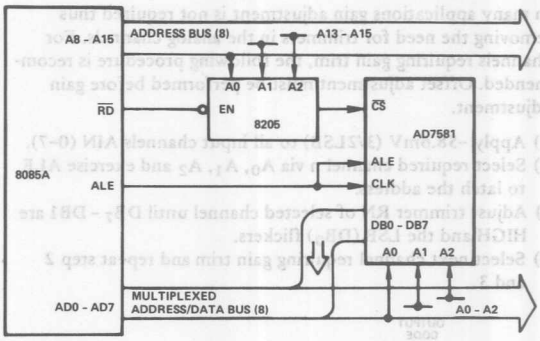

Figure 11. AD7581/8085 Interface

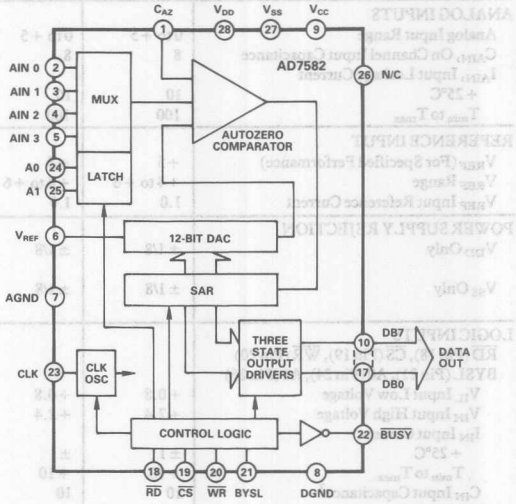
NOTES:

1. ANALOG AND DIGITAL GROUND
   It is recommended that A_{GND} and D_{GND} be connected locally to prevent the possibility of injecting noise into the AD7581. In systems where the A_{GND} – D_{GND} intertie is not local, connect back-to-back diodes (1N914 or equivalent) between the AD7581 A_{GND} and D_{GND} pins.

2. LOGIC DEGLITCHING IN μP APPLICATIONS
   Unspecified states on the address bus (due to different rise and fall times on the address bus) can cause glitches at the AD7581 $\overline{CS}$ terminal. These glitches can cause unwanted reads. The best way to avoid glitches is to gate the address decoding logic, e.g., with RD (8080), $\overline{RD}$ (8085) or VMA (6800).



CMOS 12-Bit Successive Approximation ADC

AD7582

FEATURES

- 12-Bit Successive Approximation ADC
- Four High Impedance Input Channels
- Analog Input Voltage Range of 0 to +5V with Positive Reference of +5V
- Conversion Time of 100μs per Channel
- No Missed Codes Over Full Temperature Range
- Low Total Unadjusted Error ±1LSB max
- Autozero Cycle for Low Offset Voltage
- Monolithic Construction

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7582 is a medium speed, 4-channel 12-bit CMOS A/D converter which uses the successive approximation technique to provide a conversion time of 100μs per channel. An auto-zero cycle occurs at the start of each conversion resulting in very low system offset voltages, typically less than 100μV. The device is designed for easy microprocessor interface using standard control signals; $\overline{CS}$ (decoded device address), $\overline{RD}$ ($\overline{READ}$) and $\overline{WR}$ ($\overline{WRITE}$). The 4-channel input multiplexer is controlled via address inputs A0 and A1.

Conversion results are available in two bytes, 8LSB's and 4MSB's, over an 8-bit three state output bus. Either byte can be read first. Two converter busy flags are available to facilitate polling of the converter's status.

The analog input voltage range is 0V to +5V when using a reference voltage of +5V. The four analog inputs are all high impedance inputs with tight channel-to-channel matching–typically 0.1LSBs.

PRODUCT HIGHLIGHTS

1. The AD7582 is a complete 4 channel 12-bit A/D converter in either a 28-pin DIP or 28-terminal surface mount package requiring only a few passive components and a voltage reference.
2. Autozero cycle realizes very low offset voltages, typically 100μV.
3. The four channel input multiplexer (user addressable) features high input impedance and excellent channel-to-channel matching.
4. Standard microprocessor control signals to allow easy interfacing to most popular 8- and 16-bit microprocessors.

AD7582—SPECIFICATIONS (V_{DD} = +15V, V_{CC} = +5V, V_{SS} = −5V, V_{REF} = +5.0V f_{CLK} = 140kHz external, all specifications T_{MIN} to T_{MAX} unless otherwise noted)

NOTES

[1]Temperature Range as follows: K Version; 0 to +70°C
B Version; −25°C to +85°C
T Version; −55°C to +125°C

[2]Includes Full Scale Error, Offset Error and Relative Accuracy.

[3]Sample tested to ensure compliance.

[4]I_{SINK} for $\overline{BUSY}$ (pin 22) is 1.0 milliamp.

[5]Conversion Time includes autozero cycle time.

[6]Power supply current is measured when AD7582 is inactive i.e., $\overline{WR}$ = $\overline{RD}$ = $\overline{CS}$ = $\overline{BUSY}$ = Logic HIGH.

Specifications subject to change without notice.

TIMING SPECIFICATIONS[1] (V_{DD} = +15V, V_{CC} = +5V, V_{SS} = −5V, V_{REF} = +5V)

Parameter	Limit at +25°C (All Grades)	Limit at T_{min}, T_{max} (K & B Grades)	Limit at T_{min}, T_{max} (T Grade)	Units	Conditions/Comments

	200	240	280	ns max	$\overline{RD}$ to Valid Data (Bus Access Time)
t_{14}[4]	20	20	20	ns min	$\overline{RD}$ to Three State Output
	130	160	180	ns max	(Bus Relinquish Time)

NOTES
[1]Timing Specifications are sample tested at +25°C to ensure compliance. All input control signals are specified with $t_r = t_f = 20$ns (10% to 90% of +5V) and timed from a voltage level of +1.6V. Data is timed from V_{IH}, V_{IL} or V_{OH}, V_{OL}.
[2]When using an external clock source the $\overline{WR}$ pulse width must be extended to provide the minimum auto-zero cycle time of 10µs. See "External Clock Operation".
[3]t_{13} is measured with the load circuits of Figure 3 and defined as the time required for an output to cross 0.8V or 2.4V.
[4]t_{14} is defined as the time required for the data lines to change 0.5V when loaded with the circuits of Figure 4.
Specifications subject to change without notice.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

PIN CONFIGURATIONS

DIP

PLCC

PIN FUNCTION DESCRIPTION

PIN	MNEMONIC	DESCRIPTION
1	CAZ	Autozero Capacitor Input. Connect other side of capacitor to AGND.
2	AIN 0	Analog Input, channel 0
3	AIN 1	Analog Input, channel 1
4	AIN 2	Analog Input, channel 2
5	AIN 3	Analog Input, channel 3
6	V_{REF}	Voltage reference input. The AD7582 is specified with $V_{REF} = +5.0V$.
7	AGND	Analog Ground
8	DGND	Digital Ground
9	V_{CC}	Logic Supply. For $V_{CC} = +5V$ digital inputs and outputs are TTL compatible.
10-17		Three state data outputs. They become active when $\overline{CS}$ & $\overline{RD}$ are brought low. Individual pin function is dependent upon the Byte Select (BYSL) input.

DATA BUS OUTPUT, $\overline{CS}$ & $\overline{RD}$ = LOW

	BYSL = HIGH	BYSL = LOW
Pin 10	BUSY[1]	DB7
Pin 11	LOW[2]	DB6
Pin 12	LOW[2]	DB5
Pin 13	LOW[2]	DB4
Pin 14	DB11 (MSB)	DB3
Pin 15	DB10	DB2
Pin 16	DB9	DB1
Pin 17	DB8	DB0 (LSB)

[1]BUSY (Pin 10) is a converter status flag and is HIGH during a conversion.
[2]Pins 11-13 output a logic LOW when BYSL is HIGH.
DB11–DB0 are the 12-bit conversion results, DB11 is the MSB.

18	$\overline{RD}$	READ input. This active LOW signal, in combination with $\overline{CS}$, is used to enable the output data three-state drivers.
19	$\overline{CS}$	CHIP SELECT Input. Decoded device address, active LOW. Used in combination with either $\overline{RD}$ or $\overline{WR}$ for control.
20	$\overline{WR}$	WRITE Input. This active LOW signal, in combination with $\overline{CS}$, is used to start a new conversion on a selected channel. When the AD7582 internal clock is used, the minimum $\overline{WR}$ pulse width is t2 (INT). When an external clock source is used, the minimum $\overline{WR}$ pulse width must be extended to include the autozero cycle time. For external clock operation, the minimum $\overline{WR}$ pulse width is t2 (EXT).
21	BYSL	BYTE SELECT. This control input determines whether the high or low byte of data is placed on the output data bus during a data READ operation ($\overline{CS}$ & $\overline{RD}$ LOW). See description of pins 10-17.
22	$\overline{BUSY}$	$\overline{BUSY}$ indicates converter status. $\overline{BUSY}$ is LOW during conversion, otherwise $\overline{BUSY}$ is held at a logic HIGH.
23	CLK	CLOCK Input for internal/external clock operation. Internal : Connect R_{CLK} and C_{CLK1}/C_{CLK2} timing components. See Figure 6 and Figure 7. External : Connect external 74HC compatible clock source as shown in Figure 8.
24	AO	Address Input AO. See pin 25 description.
25	A1	Address Input A1. Address inputs AO and A1 select the input channel to be converted. The address input latch is transparent when $\overline{CS}$ & $\overline{WR}$ are LOW. The address inputs are latched by $\overline{WR}$ returning HIGH.

A1	A0	CHANNEL SELECTED
0	0	AIN 0
0	1	AIN 1
1	0	AIN 2
1	1	AIN 3

26	N/C	No connect pin.
27	V_{SS}	Negative supply, −5V.
28	V_{DD}	Positive supply, +15V.

OPERATIONAL DIAGRAM

An operational diagram for the AD7582 is shown in Figure 5. The only passive components required are the autozero capacitor C_{AZ} and timing components R_{CLK}, C_{CLK1} & C_{CLK2} for the internal clock oscillator. If the AD7582 is to be used with an external clock source, then only C_{AZ} is required. Individual pin functions are described in detail on the previous page.

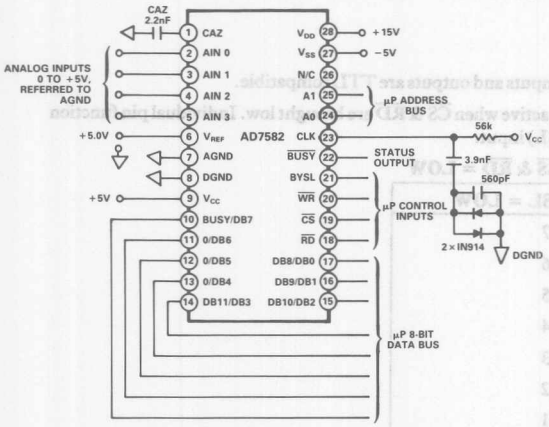

Figure 5. AD7582 Operational Diagram

INTERNAL CLOCK OPERATION

The clock circuitry for internal clock operation is shown in Figure 6 and the AD7582 operating waveforms are shown in Figure 7.

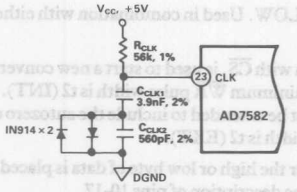

Figure 6. Circuitry Required for Internal Clock Operation

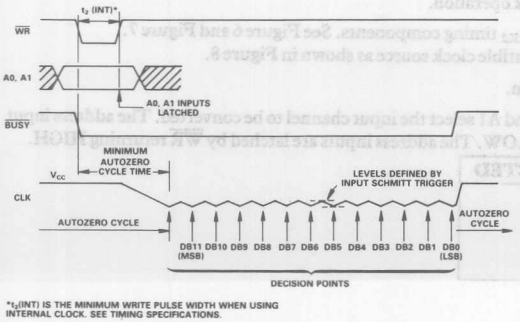

Figure 7. Operating Waveforms – Internal Clock

between conversions (BUSY = HIGH) the AD7582 is in the autozero cycle. When $\overline{WR}$ goes LOW (with $\overline{CS}$ LOW) to start a new conversion, the input multiplexer is switched to the selected channel N, via address inputs A0, A1. The autozero capacitor C_{AZ} now charges to AIN N–V_{OS} where V_{OS} is the input offset voltage of the autozero comparator.

A minimum time of 10μs is required for this autozero cycle. In applications using the internal clock oscillator, it is not necessary for $\overline{WR}$ to remain LOW for this period of time since it is automatically provided by the AD7582. This is achieved by switching a constant current load across the clock capacitors, C_{CLK1} and C_{CLK2}, causing the voltage at the CLK input pin to slowly decay from V_{CC}. This occurs after $\overline{WR}$ returns HIGH; $\overline{WR}$ returning HIGH also latches the multiplexer address inputs A0, A1 (see Figure 7). The Schmitt trigger circuit monitoring the voltage on the CLK input ends the autozero cycle when its LOW input trigger level is reached. At this point, the constant current load across the clock capacitors is removed allowing them to charge towards V_{CC} via R_{CLK}. When the voltage at the CLK input reaches the HIGH trigger level, the constant current load is replaced across C_{CLK1} and C_{CLK2}. The MSB decision is made when the LOW trigger level is reached. This cycle repeats itself 12 times to provide 12 clock pulses for the conversion cycle. The circuit arrangement of Figure 6 provides the relatively slow autozero cycle time at the beginning of a conversion while allowing the clock oscillator to speed up once the autozero cycle is complete.

EXTERNAL CLOCK OPERATION

For external clock operation R_{CLK}, C_{CLK1} and C_{CLK2} are discarded and the CLK input is driven from a 74HC compatible clock source. The mark/space ratio of the external clock can vary from 40/60 to 60/40. The AD7582 $\overline{WR}$ pulse width must now be extended to provide the minimum autozero cycle time of 10μs since this is no longer provided automatically by the AD7582. Referring to the operating waveforms of Figure 9, the minimum $\overline{WR}$ pulse width when using an external clock source is t_2 (EXT). Multiplexer address inputs A0 and A1, in addition to the $\overline{CS}$ input must now remain valid for the external $\overline{WR}$ pulse width. One approach to stretching the available μP signals is shown in the general 8-bit μP interface circuit of Figure 20. It is not necessary to synchronize the external clock source with the extended $\overline{WR}$ pulse width, the MSB decision being made on the second falling edge of the clock input after the $\overline{WR}$ input returns HIGH.

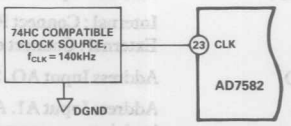

Figure 8. External Clock Operation

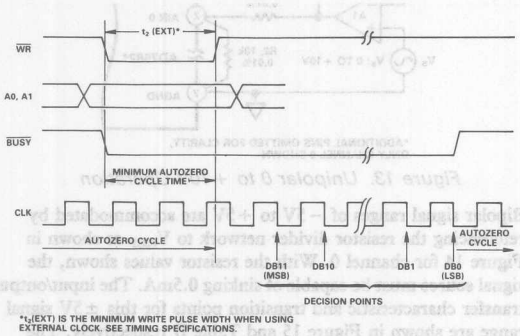

Figure 9. Operating Waveforms – External Clock

READING DATA

The 12-bit conversion data plus a converter status flag are available over an 8-bit wide data bus. Data is transferred from the AD7582 in right-justified format (i.e., the LSB is the most right-hand bit in a 16-bit word). Two READ operations are required, the Byte Select (BYSL) input determining which byte–8 least significant bits or 4 most significant bits plus status flag–is to be read first.

Since the AD7582 uses the successive approximation register (SAR) to hold conversion results (refer to Functional Diagram), it is necessary to wait until a conversion is finished before reading valid 12-bit data. Executing a READ instruction (HIGH or LOW byte) to the AD7582 while a conversion is in progress will place the existing contents of the SAR onto the data bus. Three different approaches can ensure valid 12-bit data is available for reading.

1. Insert a software delay greater than the ADC conversion time between the conversion start instruction and the data read instructions.
2. At user-defined intervals after a conversion start instruction, poll the internal converter status flag, BUSY. This signal is available on pin 10 during a HIGH byte READ instruction and is the most left-hand bit in a 16-bit right-justified word. The status bit can be shifted into a microprocessor's accumulator-carry position for testing (BUSY is HIGH during conversion).
3. Use the externally available $\overline{\text{BUSY}}$ (pin 22) signal as an interrupt to the microprocessor. This signal is LOW during a conversion and returns HIGH at conversion end.

Executing a WRITE instruction while conversion is in progress will restart the conversion.

COMPONENT SELECTION

1. Autozero Capacitor, C_{AZ}

   The autozero capacitor must be a low leakage, low dielectric absorption type such as polystyrene, polypropylene or teflon. To minimize noise connect the outside foil of C_{AZ} to AGND (pin 7), the analog system ground. C_{AZ} should be 2,200pF.

2. Clock Oscillator Components, R_{CLK}, C_{CLK1} and C_{CLK2}

   Clock pulses are generated by the action of series connected capacitors, C_{CLK1} and C_{CLK2} charging through an external resistor R_{CLK} and discharging through an internal switch. Nominal conversion time versus temperature for the recommended R_{CLK} and C_{CLK1}/C_{CLK2} combination is shown in Figure 10. Due to process variations, the actual operating frequency for this R_{CLK} and C_{CLK1}/C_{CLK2} combination can vary from device to device by up to 20%. For this reason, Analog Devices recommends using an external clock in the following situations:

   a. Applications requiring a conversion time which is within 20% of 100µs, the minimum conversion time for specified accuracy (a 140kHz clock frequency gives a 100µs conversion time).

   b. Applications which cannot accommodate conversion time differences which may occur due to unit clock frequency variations or temperature variations.

   It is possible to replace the fixed R_{CLK} resistor with a 50k potentiometer in series with a fixed 22kΩ resistor to allow individual adjustment of internal clock frequency in applications where 100µs conversion times are required. Reducing the value of R_{CLK} from 56k to 47k decreases the conversion time by typically 15µs.

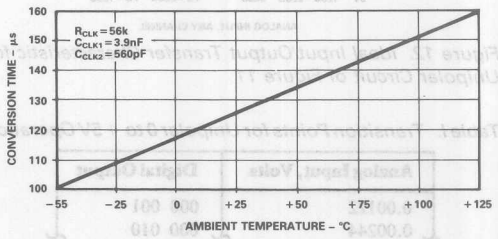

Figure 10. Typical Conversion Time vs. Temperature Using Internal Clock

APPLYING THE AD7582

The high input impedance of the analog channels, AIN0–AIN3, allows simple analog interfacing. Zero to +5V signal sources can be connected directly to the analog input channels without additional buffering for source impedances up to 5kΩ (see Figure 11). The input/output transfer characteristic and transition points for this input signal range are shown in Figure 12 and Table I respectively. The designed transition points on the AD7582 transfer characteristic occur on integer multiples of 1LSB. The output code is Natural Binary with 1LSB = (F.S.) (1/4096) = (5/4096)V = 1.22mV.

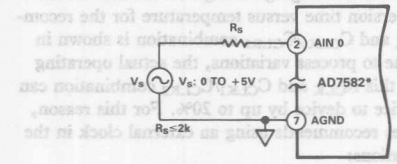

Figure 11. Unipolar 0 to +5V Operation

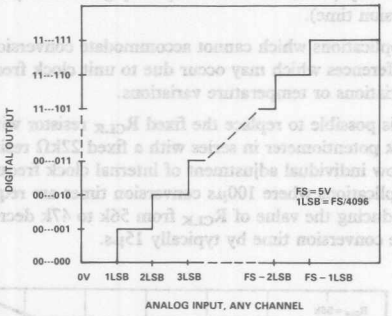

Figure 12. Ideal Input/Output Transfer Characteristic for Unipolar Circuit of Figure 11

Table I. Transition Points for Unipolar 0 to +5V Operation

Analog Input, Volts	Digital Output
0.00122	000 001
0.00244	000 010
2.49878	011 111
2.50000	100 000
2.50122	100 001
4.99756	111 110
4.99878	111 111

Signal ranges other than 0 to +5V are easily accommodated by using resistor divider networks to produce 0 to +5V signal ranges at the AD7582 input pins. Figure 13 shows a divider network on channel 0 to allow an AIN 0 signal range of 0 to +10V. The input resistors must be selected to match within 0.01% and should be the same type and from the same manufacturer so that their temperature coefficients match. Note that since the source impedance has not been included in the resistor divider ratio, it must now be as low as possible. For Figure 13 with a source impedance of 0.5Ω the maximum error across the network is approximately 0.5LSB. The LSB size is (F.S.)(1/4096) = (10/4096)V = 2.44mV.

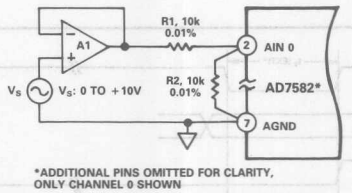

Figure 13. Unipolar 0 to +10V Operation

Bipolar signal ranges of −5V to +5V are accommodated by referencing the resistor divider network to V_{REF} as shown in Figure 14 for channel 0. With the resistor values shown, the signal source must be capable of sinking 0.5mA. The input/output transfer characteristic and transition points for this ±5V signal range are shown in Figure 15 and Table II respectively. The output code is Offset Binary with an LSB size of (F.S.)(1/4096) = (10/4096)V = 2.44mV.

With an analog input (V_S) of −1.22mV, the input offset voltage of A1 should be adjusted until the ADC output flickers between 0111 1111 1111 and 1000 0000 0000. Alternatively the −1/2LSB signal offset can be included in the signal conditioning electronics.

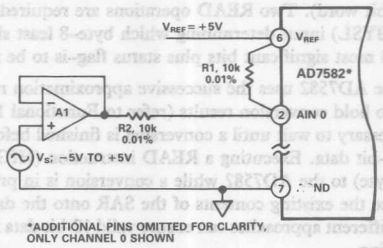

Figure 14. Bipolar −5V to +5V Operation

Table II. Transition Points for Bipolar −5V to +5V Operation

Analog Input, Volts	Digital Output
−4.99878	000 001
−4.99634	000 010
−0.00122	100 000
+0.00122	100 001
+4.99389	111 110
+4.99634	111 111

Applications

Power Supply Decoupling: All power supplies to the AD7582 should be bypassed with either 10μF tantulum or electrolytic capacitors. To ensure good high frequency performance, each capacitor should be bypassed with an 0.01μF disc ceramic capacitor. All capacitors should be placed as close as possible to the AD7582.

Reference Circuit: Figure 16 shows how to configure an AD584LH to produce a reference voltage of 5.00V. R2 provides a typical adjustment range of ±75mV. The AD584LH will contribute less than 1LSB of gain error over the commercial temperature range.

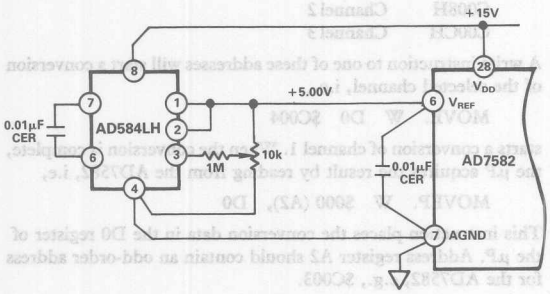

Figure 16. AD584LH as Reference Generator

Transient currents flow at the V_{REF} input during a conversion. To avoid dynamic errors place a 0.01μF disc ceramic from the V_{REF} pin to AGND.

Proper Layout: Layout for a printed circuit board should ensure that digital and analog signal lines are separated as much as possible. In particular, care should be taken not to run any digital track alongside an analog signal track or close to the autozero capacitor. The analog inputs, the reference input and the autozero input should be screened by AGND.

A single point analog ground separate from the logic system ground should be established at pin 7 (AGND) or as close as possible to the AD7582. This single point analog ground should be connected to the digital system ground, to which pin 8 (DGND) is connected, at one point only and as close to the AD7582 as possible. The autozero capacitor, bypass capacitors for the reference input and the analog supplies, AIN commons and any input signal screening should be returned to the analog ground point. Low impedance analog and digital power supply common returns are essential to low noise operation of the ADC and the foil width for these tracks should be as wide as possible.

Noise: Input signal leads to AIN 0-3 and signal return leads from AGND (pin 7) should be kept as short as possible to minimize input noise coupling. In applications where this is not possible, a shielded cable between source and ADC is recommended. Also since any potential difference in grounds between the signal source and ADC appears as an error voltage in series with the input signal, attention should be paid to reducing the ground circuit impedances as much as possible.

In applications where the AD7582 data outputs are connected to a continuously busy (and noisy) microprocessor bus it is possible to get LSB errors in conversion results. These errors are due to feedthrough from the microprocessor bus to the autozero comparator. The problem exists only for ceramic package versions of the AD7582, the electrically isolated metal lid acting like a conductor to distribute the digital noise around the package.

Grounding the lid to DGND eliminates this problem. Alternatively the AD7582 can be isolated from the microprocessor bus by means of three-state buffers.

Microprocessor Interfacing

MICROPROCESSOR INTERFACING

When the AD7582 is used with its own internal clock oscillator, microprocessor interfacing is straightforward and requires at most a few external gates (see Figures 17 through 19, 21 and 22). When the AD7582 is used with an external clock source, additional circuitry is required to extend the μP control signals (see Figure 20).

MC6800, MC6809 and 6502 MICROPROCESSORS

A typical interface to the AD7582 with any of the above microprocessors is shown in Figure 17. The decoder can be enabled high using VMA in 6800 systems or enabled low by NOR'ing ϕ_0 and ϕ_2 in 6502 systems or by NOR'ing E and Q in 6809 systems. Address lines A0, A1, and A2 of the 6800 have been tied to A0, A1 and BYSL respectively of the AD7582. Assuming the AD7582 is assigned a memory block starting at address 8000H, the input multiplexer is addressed as follows:

8000H	Channel 0
8001H	Channel 1
8002H	Channel 2
8003H	Channel 3

A write instruction to one of these addresses will start a conversion of the selected channel. To read the conversion results, it is necessary only to bring control inputs $\overline{CS}$ and $\overline{RD}$ low. The BYSL input (tied to A2 of the μP) determines whether the data high or low byte is placed onto the 8-bit data bus. A read instruction to any one of the previous channel addresses will result in the low byte of data being transferred to the μP (BYSL = Low). Similarly a read instruction to any address having A2 HIGH and within the assigned memory block, e.g., 8004H, transfers the high byte of data to the μP. The converter status flag BUSY can be polled at intervals to check whether the present conversion has finished and valid 12-bit data is available. This is accomplished by the following instructions on the 6800:

```
LDA   A   $8004      Load Flag from AD7582
ASL   A              Shift Flag into Carry
BCC       FETCH      Branch to Data Fetch
                     Subroutine if BUSY is LOW
```

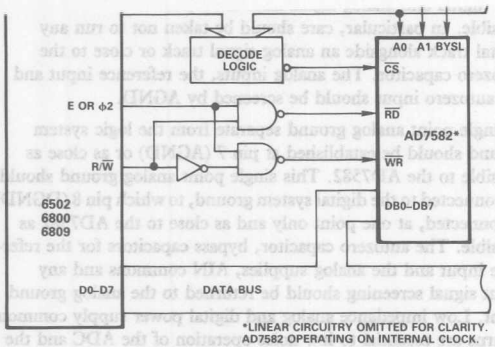

Figure 17. AD7582 – MC6800, 6809, 6502 Interface

8085A, Z80 MICROPROCESSORS

A typical interface to either of these microprocessors is shown in Figure 18. Not shown in the figure is the 8-bit latch required to demultiplex the 8085A common address/data bus. This interface uses slightly different low-level address decoding than the previous interface. Address lines A0, A1 & A2 of the µP have been tied to BYSL, A0 & A1 respectively of the AD7582. This allows the 16-bit data move instructions on both the 8085A and the Z80 to be used when reading conversion results. Assuming the AD7582 is again assigned a memory block starting at address 8000H the input multiplexer is now addressed as follows:

8000H	Channel 0
8002H	Channel 1
8004H	Channel 2
8006H	Channel 3

A write instruction to one of these addresses will start a conversion of the selected channel. The 12-bit conversion results can be read (low byte first then high byte) by a single read instruction;

On the 8085A

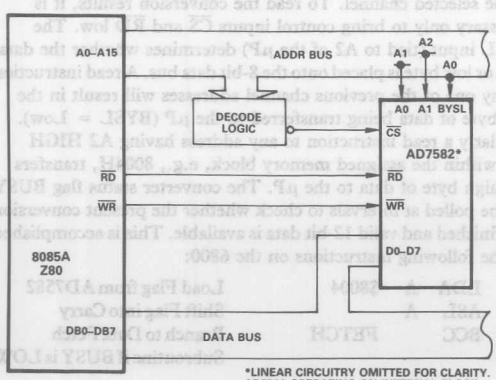

Figure 18. AD7582 – 8085A, Z80 Interface

LD BC, (8000)

moves the conversion results into register pair BC

MC68000, MC68008 MICROPROCESSOR

Figure 19 shows an AD7582–MC68000/MC68008 interface.

Address lines A1, A2 and A3 of the µP are connected to BYSL, A0 & A1 inputs respectively of the AD7582.

With the simple decoding logic shown in Figure 19, the AD7582 is decoded in a memory block from C000H to FFFFH. The input multiplexer is now addressed as follows:

C000H	Channel 0
C004H	Channel 1
C008H	Channel 2
C00CH	Channel 3

A write instruction to one of these addresses will start a conversion of the selected channel, i.e.,

MOVE. W D0 $C004

starts a conversion of channel 1. When the conversion is complete, the µP acquires the result by reading from the AD7582, i.e,

MOVEP. W $000 (A2), D0

This instruction places the conversion data in the D0 register of the µP. Address register A2 should contain an odd-order address for the AD7582, e.g., $C003.

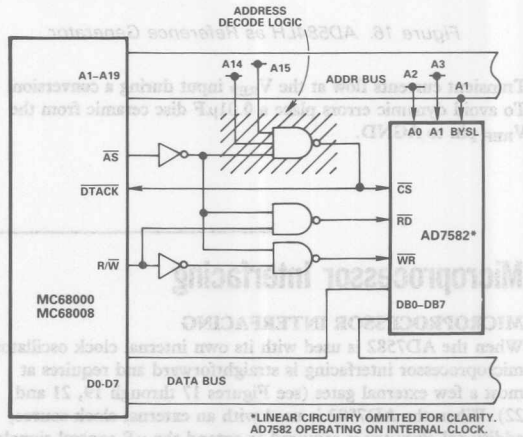

Figure 19. AD7582 – MC68000/MC68008 Interface

MICROPROCESSOR INTERFACE TO AD7582 WITH EXTERNAL CLOCK

Figure 20 shows the additional circuitry generally required to interface an 8-bit µP to the AD7582 operating from an external clock source. During a write operation, the 74121 monostable (one-shot) is triggered to latch the data (A0, A1 and $\overline{CS}$) in the 7477, a 4-bit bistable latch. The monostable timing components (not shown in Figure 20) should be chosen to provide an output pulse width corresponding to t_2 (EXT), the minimum autozero cycle time. To avoid any possibility of spurious triggering, the monostable should be enabled by a valid memory address signal. During a data read cycle, the 7477 latch is transparent and data is read normally. Note that the µP write and read cycle times are unaffected by the interface circuitry.

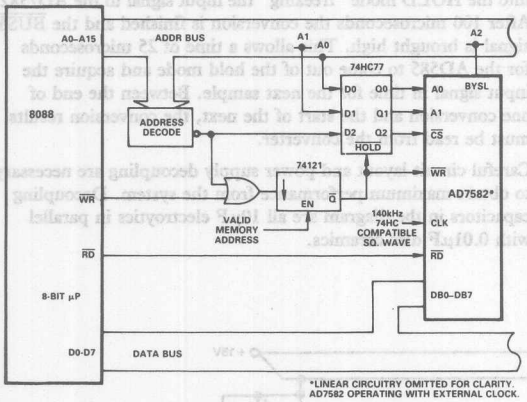

Figure 20. Interface to AD7582 Using External Clock

8088, 8086 MICROPROCESSORS

Figure 21 shows an AD7582–8088 interface.

Address lines A0, A1 and A2 are connected to BYSL, A0 and A1 inputs respectively of the AD7582. With the simple decoding shown in Figure 21 the AD7582 is decoded in a memory block from 4000H to 7FFFH. The input multiplexer is now addressed as follows:

4000H	Channel 0
4002H	Channel 1
4004H	Channel 2
4006H	Channel 3

A write instruction to one of these addresses will start a conversion of the selected channel, i.e,

MOV 4004, AX

starts a conversion of channel 2. When the conversion is finished the 8088 acquires the result by reading from the AD7582, i.e.,

MOV AX, 4000

places the conversion data in the accumulator.

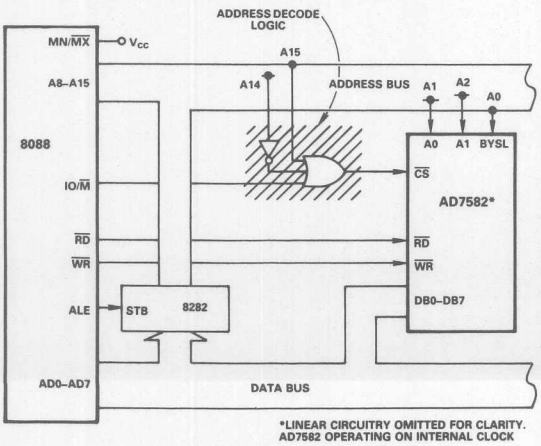

Figure 21. AD7582 – 8088 Interface

Figure 22 shows an AD7582–8086 interface. Address lines A1, A2 and A3 are connected to BYSL, A0 and A1 inputs respectively of the AD7582. The AD7582 is again decoded in a memory block from 4000H to 7FFFH. The input multiplexer is now addressed as follows:

4000H	Channel 0
4004H	Channel 1
4008H	Channel 2
400CH	Channel 3

A write instruction to one of these addresses will start a conversion of the selected channel, i.e,

MOV 4008, AX

starts a conversion of channel 2. When the conversion is finished, the 8086 acquires the result by reading from the AD7582 in two read cycles, i.e.,

MOV AL, 4000
MOV AH, 4002

places the conversion data in the accumulator.

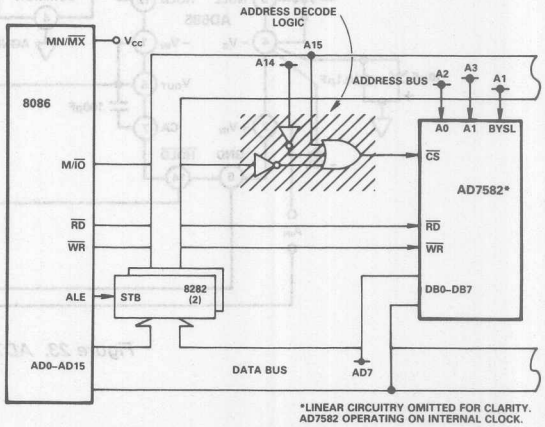

Figure 22. AD7582 – 8086 Interface

AD7582-AD585 SAMPLE-HOLD INTERFACE

Figure 23 shows an AD585 Sample-Hold Amplifier driving A_{IN1} of the AD7582. At a sampling frequency of 8kHz the maximum input signal frequency is 4kHz. The AD7582 is configured for bipolar operation to allow an input signal swing of ±5V. No clock components are shown for the AD7582 but the conversion time of the AD7582 should be adjusted for 100 microseconds. With an external hold capacitor of 100pF, the acquisition time for the sample-hold amplifier is 10 microseconds. The circuit operates from 0°C to +70°C.

To take a sample of the input, a WRITE instruction is executed to the AD7582 control inputs. The converter busy flag, $\overline{BUSY}$, is driven low indicating that a conversion is in progress. The falling edge of this $\overline{BUSY}$ signal places the sample-hold amplifier into the HOLD mode "freezing" the input signal to the AD7582. After 100 microseconds the conversion is finished and the $\overline{BUSY}$ signal is brought high. This allows a time of 25 microseconds for the AD585 to come out of the hold mode and acquire the input signal in time for the next sample. Between the end of one conversion and the start of the next, the conversion results must be read from the converter.

Careful circuit layout and power supply decoupling are necessary to obtain maximum performance from the system. Decoupling capacitors in the diagram are all 10μF electroytics in parallel with 0.01μF disc ceramics.

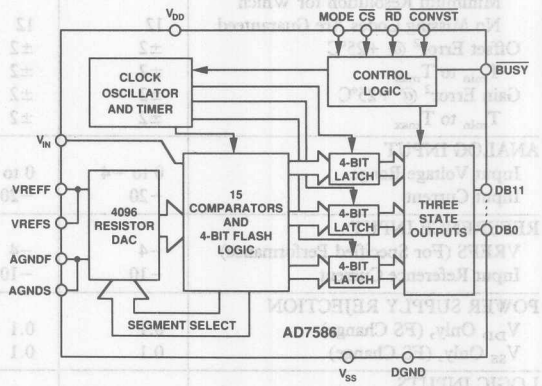
LC²MOS 12-Bit 1 µs ADC

AD7586



FEATURES

1 µs Conversion Time
AGND and VREF Force/Sense Connections
12-Bit Monotonic over Temperature
Low Power – 200 mW typ
Fast Bus Access Time – <57 ns

APPLICATIONS

Measurement and Control
Automatic Test Equipment
Precision Servo Control
All Data Acquisition Systems

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7586 is a very fast 12-bit ADC that operates from ±5 V power supplies, offering high-speed performance combined with low power dissipation. The AD7586 is a triple-pass flash ADC, which uses 15 comparators in a 4-bit flash technique to achieve 12-bit accuracy in 1 µs conversion time. Each of the 4096 quantization voltage levels are realized internally with a precision resistor DAC. The use of thin-film resistor technology and on-chip force and sense amplifiers ensure 12-bit performance.

The AD7586 has a facility to force/sense the AGND and VREF inputs minimizing offset and gain errors. The precision resistor DAC with its excellent temperature drift characteristics combined with 12-bit accurate comparators provide 12-bit linearity over the entire temperature range.

The AD7586 has a high-speed digital interface with three-state data outputs. Data access and conversion start functions are controlled by $\overline{CS}$ and $\overline{RD}$ inputs, standard microprocessor signals. Conversion control can also be provided by a $\overline{CONVST}$ input for DSP applications. The data access time of less than 57 ns means that the AD7586 can interface directly to most modern microprocessors including DSP processors.

The AD7586 is fabricated in Analog Devices' Linear Compatible CMOS process, a mixed technology process that combines precision bipolar circuits with low power CMOS logic.

PRODUCT HIGHLIGHTS

1. Fast 1 µs Conversion Time.
   Fast 1 µs conversion time makes the AD7586 suitable for a wide range of data acquisition applications.
2. Fast Microprocessor Interface.
   Standard control signals, $\overline{CS}$ and $\overline{RD}$, and fast bus access times make the AD7586 easy to interface to microprocessors
3. Low Power.
   LC²MOS fabrication process gives low power dissipation of 200 mW typically.

NOTES

[1]Timing Specifications in **bold print** are 100% production tested. All other times are sample tested at +25°C to ensure compliance. All input signals are specified with $t_r = t_f$ = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

[2]t_4 is derived from the measured time taken by the data outputs to change by 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove the effects of charging or discharging the 100 pF capacitor. This means that the time, t_4, quoted in the timing characteristics is the true bus relinquish time of the part and as such is independent of external bus loading capacitances.

[3]t_8 is measured with the load circuit of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.

Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS[1]

(T_A = +25°C unless otherwise noted)

V_{DD} to AGND . . . . . −0.3 V to +7 V
V_{SS} to AGND[2] . . . . . +0.3 V to −7 V
AGND to DGND . . . . . −0.3 V to V_{DD} +0.3 V
V_{IN} to AGND . . . . . V_{SS} −0.3 V to V_{DD} +0.3 V
VREFF, VREFS to AGND . . . . . V_{SS} −0.3 V to V_{DD} +0.3 V
Digital Inputs to DGND
$\overline{CS}$, $\overline{RD}$, $\overline{CONVST}$, Mode . . . . . −0.3 V to V_{DD} +0.3 V
Digital Outputs to DGND
DB0 to DB11, $\overline{BUSY}$ . . . . . −0.3 V to V_{DD} +0.3 V
Operating Temperature Range
Commercial (J, K Versions) . . . . . 0 to +70°C
Industrial (A, B Versions) . . . . . −40°C to +85°C
Extended (S Version) . . . . . −55°C to +125°C
Storage Temperature Range . . . . . −65°C to +150°C
Lead Temperature (Soldering, 10 secs) . . . . . +300°C
Power Dissipation (Any Package) to +75°C . . . . . 1000 mW
Derates above +75°C by . . . . . 10 mW/°C

[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

[2]If V_{SS} is open circuited with V_{DD} and AGND applied, the V_{SS} pin will be pulled positive, exceeding the Absolute Maximum Ratings. If this possibility exists, a Schottky diode from V_{SS} to DGND (cathode end to GND) ensures that the Absolute Maximum Ratings will be observed.

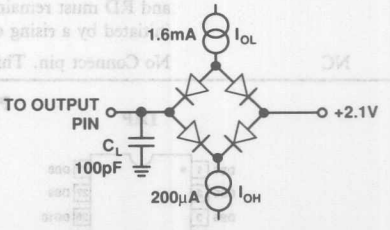

Figure 1. Load Circuit for Access and Relinquish Time

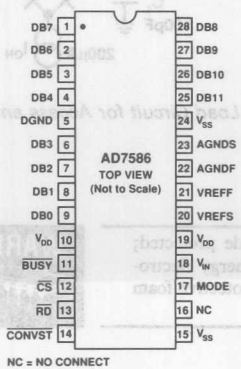
CAUTION



ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

Number	Mnemonic	Description
POWER SUPPLY		
10 & 19	V_{DD}	Positive Power Supply, +5 V ±5%. Both V_{DD} pins must be tied together.
15 & 24	V_{SS}	Negative Power Supply, −5 V ±5%. Both V_{SS} pins must be tied together.
22	AGNDF	Analog Ground Force. The input can be used in conjunction with AGNDS to force/sense the external AGND (See Figure 3). Force/sensing the AGND minimizes offset error. In applications where offset error is not important these inputs can be tied together and connected directly to the external AGND reference.
23	AGNDS	Analog Ground Sense. This is the complementary input for AGNDF (above) to force/sense the analog ground reference. AGNDF and AGNDS are tied together internally.
5	DGND	Digital Ground.
ANALOG AND REFERENCE INPUTS		
18	V_{IN}	Analog Input. The analog input range is 0 to −4 V.
20	VREFS	Voltage Reference Sense Input. The input can be used in conjunction with VREFF to force/sense an external voltage reference (See Figure 3). Force/sensing the VREF input minimizes gain error. In applications where gain error is not important these inputs can be tied together and connected directly to an external reference.
21	VREFF	Voltage Reference Force Input. This is the complementary input for VREFS (above) to force/sense an external voltage reference. VREFF and VREFS are tied together internally.
INTERFACE		
1–4, 6–9	DB7–DB4, DB3–B0	Three-state data outputs. These outputs are controlled by $\overline{CS}$ and $\overline{RD}$. DB11 is the most significant bit, (MSB).
25–28	DB11–DB8	
11	$\overline{BUSY}$	$\overline{BUSY}$ output indicates converter status. $\overline{BUSY}$ is low during conversion.
12	$\overline{CS}$	Chip Select Input. The device is selected when this input is low.
13	$\overline{RD}$	Read Input. This active low signal, in conjunction with $\overline{CS}$ is used to enable the output data three-state drivers and initiate a conversion when the MODE input pin is tied low.
CONTROL		
14	$\overline{CONVST}$	Conversion Start Input. This input may be used to start conversion when the MODE input pin is tied high.
17	MODE	Mode Input. When this pin is low, conversion is initiated on the falling edge of $\overline{CS}$ and $\overline{RD}$. $\overline{CS}$ and $\overline{RD}$ must remain low for the duration of the conversion. When this pin is high conversion is initiated by a rising edge on the $\overline{CONVST}$ input.
16	NC	No Connect pin. This pin has no internal connections.

OPERATIONAL DIAGRAM

An operational diagram for the AD7586 is shown in Figure 2. The only external component required for basic operation of the part is a −4 V reference.

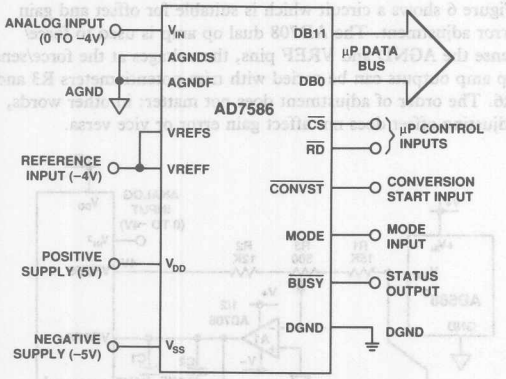

Figure 2. Operational Diagram

CONVERTER DETAILS

The AD7586 is a triple-pass flash ADC which uses 15 comparators in a 4-bit flash technique to perform the 12-bit conversion procedure. Each of the 4096 quantization levels is realized internally with a precision resistor DAC.

The fifteen comparators first compare the analog input voltage to the VREF/16 voltages of the resistor array. This determines the four most significant bits and selects 1 out of 16 voltage segments. The comparators are then switched to 15 subvoltages on that segment to determine the next four bits and select 1 out of 256 voltage segments. A further switching of the comparators to another 15 subvoltages produces the complete 12-bit conversion result. The 12 bits of data are then stored internally in a three-state output latch.

FORCE/SENSE CONNECTIONS

The AD7586 has a facility for Kelvin (force/sense) connections on the AGND and VREF pins to minimize offset and gain errors. Force/sensing these inputs eliminates error contributions from voltage or IR drops due to resistances from nonideal, internal conductors. IR drops in the AGND path cause an offset error while IR drops in the reference path cause a gain error. Typically, the use of Kelvin connections reduces the offset and gain errors by 2 LSBs.

A low op amp offset voltage is important as any offset voltage will add directly to the voltage that is being forced/sensed. Suitable op amps for this application are precision op amps such as the AD705, AD707 or the AD708 (dual op amp), all of which feature offset voltages of less than 100 µV.

REFERENCE INPUT

The AD7586 operates from a −4 V external reference. Figure 3 shows a typical reference connection circuit based on the AD586. The AD586 is a high performance voltage reference which exhibits excellent stability performance, 5 ppm/°C max. The AD586's +5 V output is scaled and inverted before being applied to the AD7586 VREF inputs. Proper decoupling on the force/sense op amp outputs is important to suppress high speed transients during the conversion procedure. Note, connecting capacitors directly to op amp outputs can cause stability problems. However, the use of large capacitors, 10 µF in Figure 3, limits the open-loop bandwidth preventing any closed-loop oscillations.

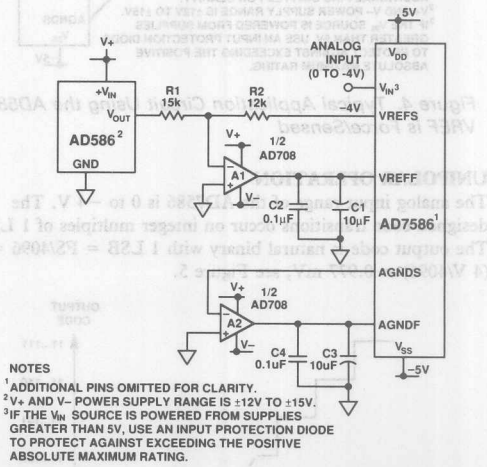

Figure 3. Typical Application Circuit Using the AD586, AGND and VREF Are Force/Sensed

Where offset and gain errors are not important, the force/sense op amps can be omitted and the force/sense pins can be tied together as shown for the AGND connection in Figure 4. However the reference circuitry will invariably use an external op amp to scale the reference input voltage to −4 V, this op amp can provide the second function of force/sensing at no extra cost. In all applications, both the AGND and the VREF pins must be driven from low impedance sources.

The AD586 is a precision voltage reference used for applications throughout this data sheet. However, other references exist which may be preferable in some applications. One example is the ZNREF040, 4 V reference, available from Plessey Semiconductor. This part is not as suitable for precision applications, its temperature drift specification is 50 ppm/°C. It does have the advantage of a smaller package size, 3-pin metal can.

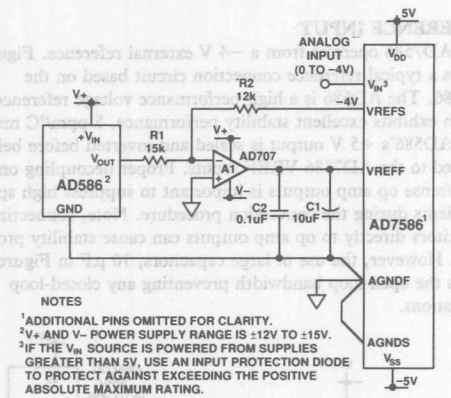

Figure 4. Typical Application Circuit Using the AD586, VREF is Force/Sensed

UNIPOLAR OPERATION

The analog input range of the AD7586 is 0 to −4 V. The designed code transitions occur on integer multiples of 1 LSB. The output code is natural binary with 1 LSB = FS/4096 = (4 V/4096) = 0.977 mV, see Figure 5.

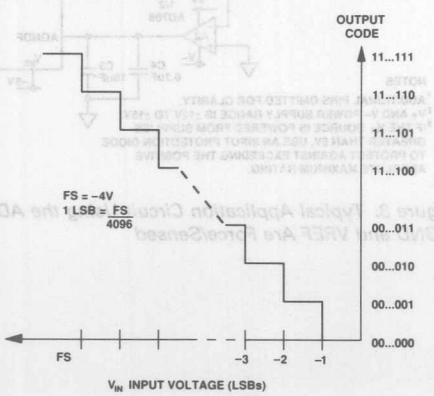

Figure 5. AD7586 Transfer Function

UNIPOLAR OFFSET AND GAIN ERROR ADJUST

Both offset and gain errors are less than 2 LSBs, when force/sense amplifiers are used for the reference and AGND pins, eliminating the need for calibrating the AD7586 in the majority of cases. However, applications requiring absolute accuracy may use the force/sense amplifiers to null any system offset or gain errors caused by signal conditioning or other external circuitry.

The overall transfer function can be calibrated as a "mid riser" type or a "mid tread" type. A mid riser type is where the code transitions occur on successive integer LSB values, the mid tread type is where the code transitions occur mid way between successive integer LSB values. The only difference between the two types is a 1/2 LSB offset, the first and last code transition voltages are shown below in Table I.

	Mid Tread	Mid Riser
First Code Transition Voltage (0000 0000 0000 to 0000 0000 0001)	−0.488 mV	−0.977 mV
Last Code Transition Voltage (1111 1111 1110 to 1111 1111 1111)	−3.9985 V	−3.9990 V

Table I. Ideal First and Last Transition Voltages for Unipolar Operation

Figure 6 shows a circuit which is suitable for offset and gain error adjustment. The AD708 dual op amp is used to force/sense the AGND and VREF pins, the voltages at the force/sense op amp outputs can be varied with trim potentiometers R3 and R6. The order of adjustment does not matter; in other words, adjusting offset does not affect gain error or vice versa.

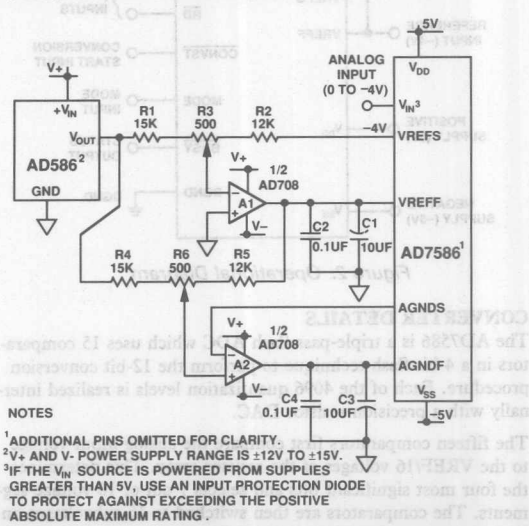

Figure 6. Unipolar Operation with Full-Scale Adjustment

Offset adjustment is achieved by adjusting the AGND force/sense voltage. To adjust the offset apply the first code transition voltage to V_{IN} (see Table I) and adjust R6 until the ADC output code flickers between 0000 0000 0000 and 0000 0000 0001.

Gain error can be nulled by adjusting the reference input which in turn adjusts the full-scale digital output. To adjust the full-scale output apply the last code transition voltage at V_{IN} and vary R3 until the output code flickers between 1111 1111 1110 and 1111 1111 1111.

BIPOLAR OPERATION

Figure 7 shows how bipolar operation can be achieved with the AD7586. The circuit uses an op amp to offset the analog signal by −2 V before being applied to the AD7586 analog input. The circuit has an analog input range of ±2 V with an LSB size of 0.997 mV. The output code is offset binary, see Figure 8 for the transfer function.

Signal ranges other than ±2 V are easily accommodated by using a different value of R3. For example, setting R3 equal to 30 k increases the analog input range to ±5 V. R3 should always be chosen such that the voltage range at V_{IN} covers the full dynamic range (0 to −4 V) of the ADC. All resistors should be the same type and from the same manufacturer so that their temperature coefficients match.

For ac sampling applications it is possible to substitute the op amp, A1, for a sample-and-hold amplifier SHA. Not all SHAs have both the inverting and noninverting terminals available to the user in which case the op amp is still necessary to level shift the analog input.

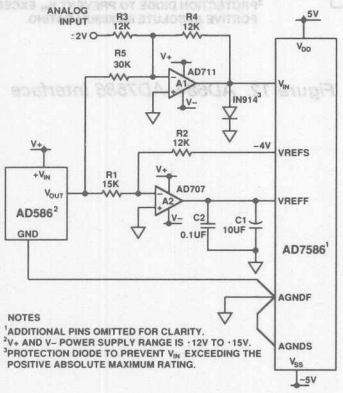

Figure 7. AD7586 Bipolar Operation

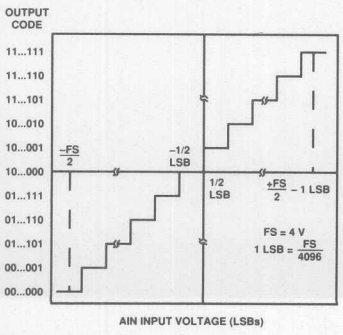

Figure 8. Ideal Input/Output Transfer Function for the Circuit of Figure 7

BIPOLAR OFFSET AND GAIN ERROR ADJUST

For applications where absolute accuracy is important then system offset and gain errors can be adjusted to zero using the force/sense amplifiers as in the unipolar case. In the case of Figure 7, one source of gain error is the resistor mismatch between R3 and R4. This error in conjunction with other gain error sources can be nulled by making either R2 or R3 variable and using the same adjustment procedure as discussed for the unipolar circuit. For offset adjustment, an AGND force/sense amplifier is needed with the same resistor biasing and trim arrangement as that shown in Figure 6 (R4, R5 and R6). Again, the adjustment procedure is the same as that discussed for Figure 6. Note, the analog input signal is level shifted by −2 V, therefore, −2 V must be subtracted from the first and last code transition voltages listed in Table I before being applied to this circuit.

TIMING AND CONTROL

Conversion start and data access are controlled by four digital inputs: $\overline{CS}$, $\overline{RD}$, $\overline{CONVST}$ and MODE. There are two basic modes of operation, Mode 0 and Mode 1 which are shown in Figures 9 to 11. Mode 0 is designed for applications where a microprocessor has complete control over conversion start and data access. Mode 1 is designed for DSP applications where a timer controls conversion start, ensuring equal sampling intervals, while data access is again controlled by a microprocessor. The AD7586 MODE input pin selects the timing mode: MODE = 0 V for Mode 0 and MODE = 5 V for Mode 1.

Mode 0 (MODE = 0 V)

For direct bus interfacing using Mode 0, the microprocessor must have a WAIT state facility. A read operation to the ADC brings $\overline{CS}$ and $\overline{RD}$ low which triggers a conversion. The AD7586 acknowledges by bringing $\overline{BUSY}$ low indicating that conversion is in progress. $\overline{BUSY}$ returns high at the end of conversion when the ADC's output latches have been updated and the conversion result is placed on the data outputs. Note the data bus is in the three-state condition for the duration of the conversion and becomes active before $\overline{BUSY}$ goes high (see t_3, Figure 9) at the end of conversion.

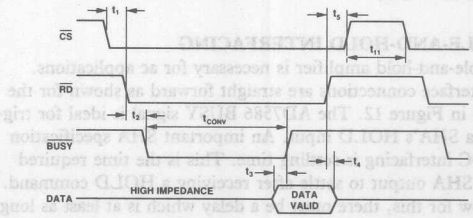

Figure 9. Mode 0 Timing Diagram (Mode = 0 V)

Mode 1 (MODE = 5 V)

In this mode conversion is started by asserting the $\overline{CONVST}$ input (see Figure 10). $\overline{BUSY}$ goes low after the falling of the $\overline{CONVST}$ input. However, the ADC conversion procedure does not start until after the rising of the $\overline{CONVST}$ pulse. $\overline{BUSY}$ returns high when conversion is complete. The total width of the $\overline{BUSY}$ pulse is equal to the $\overline{CONVST}$ pulse width plus the ADC conversion time. Note, the time t_{CONV} is typically 30 ns larger in Mode 1 than in Mode 0. Data can be read by a microprocessor any time after the rising edge of $\overline{BUSY}$. Note that pulsing $\overline{CONVST}$ low while a conversion is in progress will initiate a new conversion.

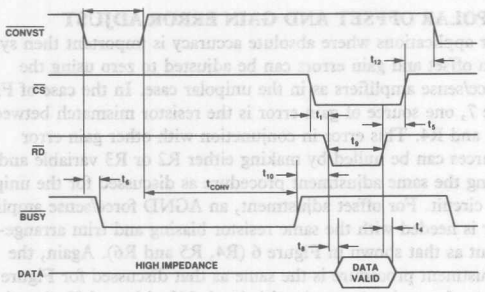

Figure 10. Mode 1 Timing Diagram (Mode = 5 V)

Figure 11 shows a variation of Mode 1 timing that is useful when external latches are used to store the conversion results. In this case, $\overline{CS}$ and $\overline{RD}$ are tied permanently low and the data bus is always active, except when $\overline{BUSY}$ is low. The data bus is in the three-state condition during the $\overline{BUSY}$ low state. The data bus then becomes active just before $\overline{BUSY}$ returns high at the end of conversion, so that $\overline{BUSY}$ can be used as a clocking signal for external latches.

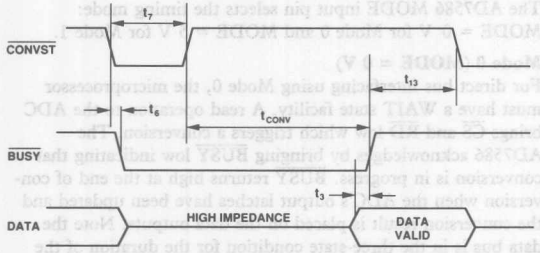

Figure 11. Mode 1 Timing Diagram, $\overline{CS}$ = $\overline{RD}$ = 0 V (Mode = 5 V)

SAMPLE-AND-HOLD INTERFACING

A sample-and-hold amplifier is necessary for ac applications. The interface connections are straight forward as shown for the AD684 in Figure 12. The AD7586 $\overline{BUSY}$ signal is ideal for triggering a SHA's HOLD input. An important SHA specification for ADC interfacing is settling time. This is the time required by the SHA output to settle after receiving a HOLD command. To allow for this, there must be a delay which is at least as long as the SHA settling time between the HOLD command and the AD7586's first flash decision. Large hold-mode settling time can be compensated for in Mode 1. The delay between the start of a conversion and the first flash decision is approximately 200 ns. In Mode 1 timing, $\overline{BUSY}$ goes low when $\overline{CONVST}$ goes low but the conversion procedure does not start until $\overline{CONVST}$ goes high. So, the $\overline{CONVST}$ pulse width can be used to compensate for any additional SHA settling time greater than 200 ns. For example, if a SHA has a settling time of 500 ns, then the $\overline{CONVST}$ pulse width should be 300 ns.

AD684 SAMPLE-AND-HOLD

The AD684 is a quad sample-and-hold (SHA) with an acquisition time of 1 μs. Figure 12 shows the SHA coupled with the calculate the overall throughput rate, the acquisition time and the settling time of the SHA along with the ADC conversion time have to be taken into account. For the single channel system shown in Figure 12, the minimum throughput time is approximately 2.5 μs. This figure allows for 1 μs each for acquisition and conversion time and 500 ns for settling time and other overheads.

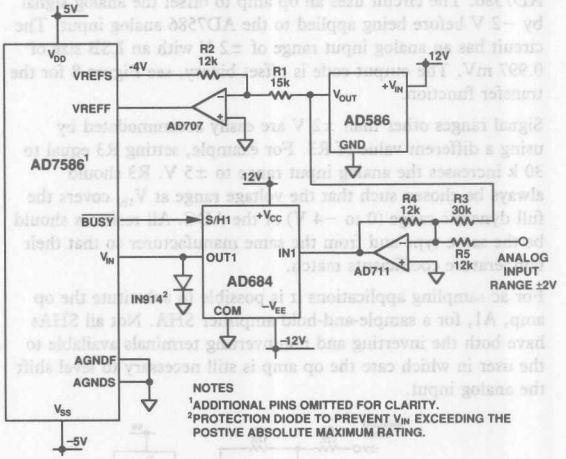

Figure 12. AD684–AD7586 Interface

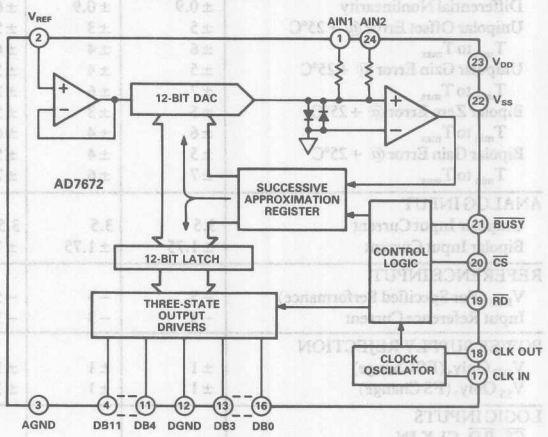

High-Speed 12-Bit ADC

AD7672

FEATURES

- 12-Bit Resolution and Accuracy
- Fast Conversion Time
  - AD7672XX03 – 3μs
  - AD7672XX05 – 5μs
  - AD7672XX10 – 10μs
- Unipolar or Bipolar Input Ranges
- Low Power: 110mW
- Fast Bus Access Times: 90ns
- Small, 0.3", 24-Pin Package and 28-Terminal Surface Mount Packages

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7672 is a high-speed 12-bit ADC, fabricated in an advanced, mixed technology, Linear-Compatible CMOS (LC^2MOS) process, which combines precision bipolar components with low-power, high-speed CMOS logic. The AD7672 uses an accurate high-speed DAC and comparator in an otherwise conventional successive-approximation loop to achieve conversion times as low as 3μs while dissipating only 110mW of power.

To allow maximum flexibility the AD7672 is designed for use with an external reference voltage. This allows the user to choose a reference whose performance suits the application or to drive many AD7672s from a single system reference, since the reference input of the AD7672 is buffered and draws little current. For digital signal processing applications where absolute accuracy and temperature coefficients may be unimportant, a low-cost reference can be used. For maximum precision, the AD7672 can be used with a high-accuracy reference, such as the AD588, when absolute 12-bit accuracy can be obtained over a wide temperature range.

An on-chip clock-circuit is provided which may be used with a crystal for accurate definition of conversion time. Alternatively, the clock input may be driven from an external source such as a microprocessor clock.

The AD7672 also offers flexibility in its analog input ranges, with a choice of 0 to +5V, 0 to +10V and ±5V.

The AD7672 is also designed to operate from nominal supply voltages of +5V and −12V. This makes it an ideal choice for data acquisition cards in personal computers where the negative supply is generally −12V.

The AD7672 has a high-speed digital interface with three-state data outputs and standard microprocessor control inputs (Chip Select and Read). Bus access time of only 90ns allows the AD7672 to be interfaced to most modern microprocessors.

The AD7672 is available in a variety of space-saving packages; plastic and hermetic 24-pin "skinny" DIP and 28-pin ceramic and plastic chip carrier.

PRODUCT HIGHLIGHTS

1. Fast, 3μs, 5μs and 10μs conversion speeds make the AD7672 ideal for a wide range of applications in telecommunications, sonar and radar signal processing or any high-speed data acquisition system.
2. LC^2MOS circuitry gives high precision with low power drain (110mW typ).
3. Choice of 0 to +5V, 0 to +10V or ±5V input ranges, accomplished by pin-strapping.
4. Fast, simple, digital interface has a bus access time of 90ns allowing easy connection to most microprocessors.
5. Available in space-saving 24-pin, 0.3" DIP or surface mount package.

AD7672—SPECIFICATIONS

(V_{DD} = 5V ± 5%, V_{SS} = −12V ± 10%, V_{REF} = −5V unless otherwise noted. f_{CLK}: 4MHz for AD7672XX03, 2.5MHz for AD7672XX05, 1.25MHz for AD7672XX10. All Specifications T_{min} to T_{max} unless otherwise noted. Specifications apply to Slow Memory Mode.)

NOTES

[1]Timing Specifications are sample tested at +25°C to ensure compliance. All input control signals are specified with tr = tf = 5ns (10% to 90% of +5V) and timed from a voltage level of 1.6V.

[2]t_3 and t_6 are measured with the load circuits of Figure 1 and defined as the time required for an output to cross 0.8V or 2.4V.

[3]t_7 is defined as the time required for the data lines to change 0.5V when loaded with the circuits of Figure 2.

*Stress above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other condition above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

TERMINOLOGY

UNIPOLAR OFFSET ERROR
The ideal first code transition should occur when the analog input is 1/2LSB above AGND. The deviation of the actual transition from that point is termed the offset error.

BIPOLAR ZERO ERROR
The ideal midscale transition (i.e., 0111 1111 1111 to 1000 0000 0000) for the ±5V range should occur when the analog input is 1/2LSB below AGND. Bipolar zero error is the deviation of the actual transition from that point.

GAIN ERROR
The ideal difference between the first code transition and last code transition is FS − 2LSBs. The Gain error is defined as the deviation between this ideal difference and the measured difference. Ideal FS corresponds to 5V for the unipolar 0 to 5V range and 10V for both the unipolar 0 to 10V and bipolar ±5V ranges.

OPERATING FROM A NEGATIVE SUPPLY GREATER THAN −12V

The AD7672 is designed to operate with a V_{SS} input of −12V ± 10%. In applications where the negative supply is greater than −12V, then a Zener diode in series with V_{SS} can be used to reduce the supply. The Zener diode should have a dynamic impedance of not greater than 40Ω. An example is given in Figure 3. The diode has a Zener voltage of 3V, which makes it suitable for a negative supply of −15V ± 7%.

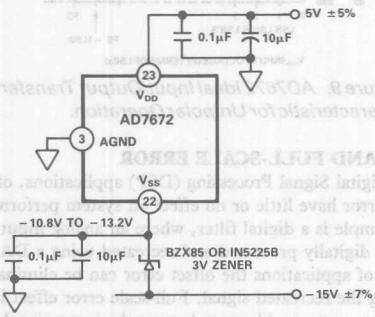

Figure 3. Operation from Nominal Power Supplies of 5V and −15V

CONVERTER DETAILS

Conversion start is controlled by the $\overline{CS}$ and $\overline{RD}$ inputs. At the start of conversion the successive approximation register (SAR) is reset and the three-state data outputs are enabled. Once a conversion cycle has begun it cannot be restarted.

During conversion, the internal 12-bit DAC is sequenced by the SAR from the most significant bit (MSB) to the least significant bit (LSB). Referring to Figure 4, the analog inputs (AIN1 & AIN2) connect to the comparator input via 5kΩ resistors. The DAC which has 2.5kΩ output impedence connects to the same comparator input. Bit decisions are made by the comparator (zero crossing detector) which checks the addition of each successive weighted bit from the DAC output against the analog inputs. The MSB decision is made 80ns (typically) after the second falling edge of CLK IN following a conversion start (see Figure 5). Similarly, the succeeding bit decisions are made approximately 80ns after a CLK IN falling edge until conversion is finished. At the end of conversion, the DAC output current balances the current from the analog inputs. The SAR contents (12-bit data word) which represent the analog input signal are loaded into a 12-bit latch.

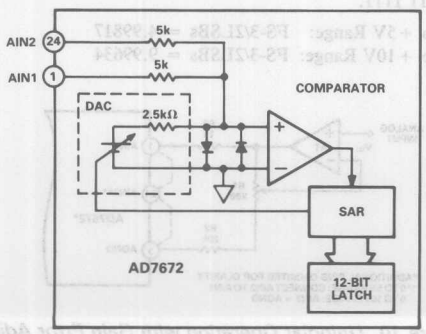

Figure 4. AD7672 AIN Input

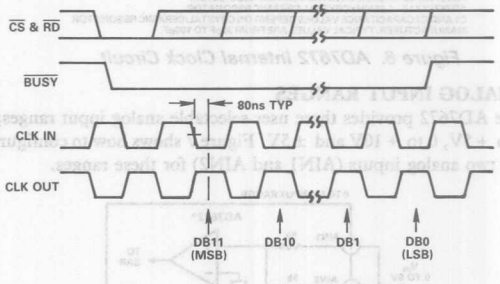

Figure 5. Operating Waveforms Using an External Clock Source for CLK IN

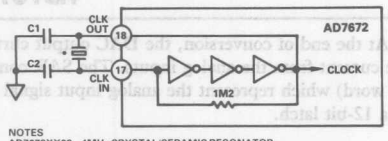
CONTROL INPUTS SYNCHRONIZATION

In applications where the $\overline{RD}$ control input is not synchronized with the ADC clock then conversion time can vary from 12 to 13 CLK IN periods. This is because the ADC waits for the first falling CLK IN edge after conversion start before the conversion procedure begins. Without synchronization, this delay can vary from zero to an entire clock period. If a constant conversion time is required, then the following approach may be used: when initiating a conversion, $\overline{RD}$ must go low on either the rising edge of CLK IN or the falling edge of CLK OUT. This ensures a fixed conversion time that is 12.5 times the CLK IN period.



DRIVING THE ANALOG INPUTS

During conversion current from the analog inputs is modulated by the DAC output current at a rate equal to the CLK IN frequency (i.e., 4MHz when CLK IN = 4MHz). This causes voltage spikes (glitches) to appear at the analog inputs. The magnitude and settling time of these glitches depends on the open-loop output impedance and small signal bandwidth of the amplifier or sample and hold driving these inputs. These devices must have sufficient drive to ensure that the glitches have settled within one clock period. An example of a suitable op amp is the AD OP-27. The magnitude of the largest glitch when using this device to drive one of the analog inputs is typically 11mV with a 200ns settling time.

Suitable devices capable of driving the AD7672 analog inputs are the AD OP-27 and AD711 op amps and the AD585 sample-and-hold.

INTERNAL CLOCK OPERATION

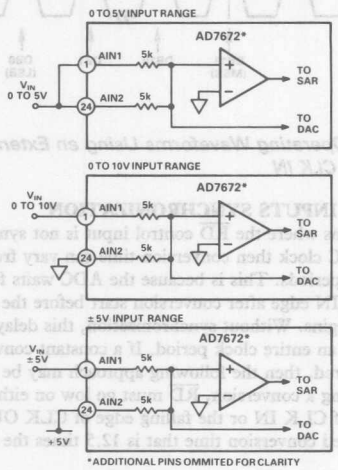
Figure 6 shows the AD7672 internal clock circuit. A crystal or ceramic resonator may be connected between CLK IN (Pin 17) and CLK OUT (Pin 18) to provide a clock oscillator for the ADC timing. Alternatively the crystal/ceramic resonator may be omitted and an external clock source may be connected to CLK IN. For an external clock the mark/space ratio must be 50/50. An inverted CLK IN will appear at the CLK OUT pin as shown in the operating waveforms of Figure 5.

NOTES
AD7672XX03 – 4MHz CRYSTAL/CERAMIC RESONATOR.
AD7672XX05 – 2.5MHz CRYSTAL/CERAMIC RESONATOR.
AD7672XX10 – 1.25MHz CRYSTAL/CERAMIC RESONATOR.
C1 AND C2 CAPACITANCE VALUES DEPEND ON CRYSTAL/CERAMIC RESONATOR MANUFACTURER. TYPICAL VALUES ARE FROM 30pF TO 100pF.

Figure 6. AD7672 Internal Clock Circuit

ANALOG INPUT RANGES

The AD7672 provides three user selectable analog input ranges; 0 to +5V, 0 to +10V and ±5V. Figure 7 shows how to configure the two analog inputs (AIN1 and AIN2) for these ranges.



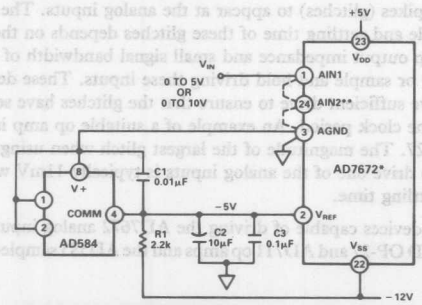


Figure 7. Analog Input Range Configurations

UNIPOLAR OPERATION

Figure 8 shows how to configure an AD584 to produce a reference voltage of −5V for unipolar operation.

*ADDITIONAL PINS OMMITED FOR CLARITY
**0-TO-5V RANGE: CONNECT AIN2 TO AIN1
0-TO-10V RANGE: AIN2 = AGND

Figure 8. Unipolar Operation Using the AD584 as a Reference

The ideal input/output characteristic is shown in Figure 9. The designed code transitions occur midway between successive integer LSB values (i.e., 1/2LSB, 3/2LSBs . . . FS −3/2 LSBs). The output code is natural binary with 1LSB = FS/4096. FS is either +5V or +10V depending on the analog inputs configuration.

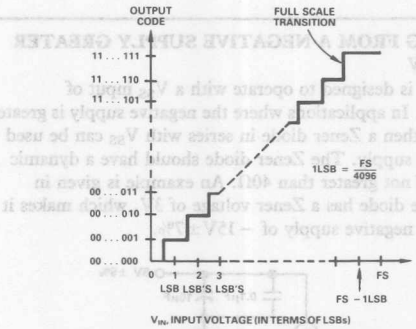

Figure 9. AD7672 Ideal Input/Output Transfer Characteristic for Unipolar Operation.

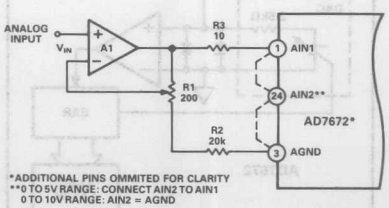
OFFSET AND FULL-SCALE ERROR

In most Digital Signal Processing (DSP) applications, offset and full-scale error have little or no effect on system performance. A typical example is a digital filter, where an analog input signal is quantized, digitally processed and recreated using a DAC. In these type of applications the offset error can be eliminated by ac coupling the recreated signal. Full-scale error effect is linear and does not cause problems as long as the input signal is within the full dynamic range of the ADC. An important consideration in DSP applications is Differential Nonlinearity and this is not affected by either offset or full-scale error.



UNIPOLAR OFFSET AND FULL-SCALE ERROR ADJUSTMENT

If absolute accuracy is an application requirement then offset and full-scale error can be adjusted to zero. Offset error must be adjusted before full-scale error. Figure 10 shows the extra components required for full-scale error adjustment. Zero offset is achieved by adjusting the offset of the op amp driving the analog input (i.e., A1 in Figure 10.). For zero offset error apply a voltage equal to 1/2LSB at V_{IN} and adjust the op amp offset voltage until the ADC output code flickers between 0000 0000 0000 and 0000 0000 0001.

0 to +5V Range: 1/2LSB = 0.61mV
0 to +10V Range: 1/2LSB = 1.22mV

For zero full-scale error apply an analog input voltage equal to FS-3/2LSBs (last code transition) at V_{IN} and adjust R1 until the ADC output code flickers between 1111 1111 1110 and 1111 1111 1111.

0 to +5V Range: FS-3/2LSBs = 4.99817
0 to +10V Range: FS-3/2LSBs = 9.99634

*ADDITIONAL PINS OMMITED FOR CLARITY
**0 TO 5V RANGE: CONNECT AIN2 TO AIN1
0 TO 10V RANGE: AIN2 = AGND

Figure 10. Unipolar Operation with Gain Error Adjust

BIPOLAR OPERATION

Bipolar operation is achieved by providing a +10V span at the AIN1 input which is offset to ±5V by applying +5V at the AIN2 input. This requires two reference voltages; −5V for the V_{REF} input and +5V for the AIN2 input. Figure 11 demonstrates how to produce these voltages from an AD584 and an inverting amplifier configuration. Alternatively, a convenient solution is to use the AD588 voltage reference as in Figure 12. This device generates the required ±5V with a minimum of additional components. It also offers excellent temperature stability with voltage drifts as low as 1.5ppm/°C.

The ideal input/output transfer characteristic after offset and gain adjustment is shown in Figure 13. The LSB size is (10/4096)V = 2.44mV.

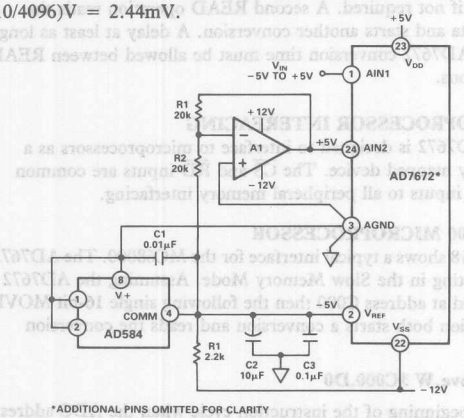


Figure 11. Bipolar Operation Using an AD584 and an AD711 Op Amp

BIPOLAR OFFSET AND GAIN ADJUSTMENT

In applications where absolute accuracy is important then offset and gain error can be adjusted to zero. Offset is adjusted by trimming the voltage at the AIN1 or the AIN2 input when the analog input is at −FS/2 +1/2LSB. This can be achieved by adjusting the offset of an external amplifier used to drive either of these analog inputs. Alternatively the AD588 voltage reference contains a balance control input which can be used to trim the offset to zero. An additional potentiometer (R2 in Figure 14) is required. The trim procedure is as follows:

Apply −4.99878V (−FS/2 + 1/2LSB) at V_{IN} and adjust R2 until the ADC ouput code flickers between 0000 0000 0000 and 0000 0000 0001.

Gain error can be adjusted at either the last positive code transition or the mid-scale transition (bipolar zero error adjust). Adjusting the positive end of the transfer function is in keeping with more conventional ADC calibration techniques where the user fixes the two end points as in the unipolar case. Bipolar zero adjustment is required in some applications (e.g., motor control) where the user must be guaranteed that the 0111 1111 1111 to 1000 0000 0000 transition occurs exactly when the analog input is 1/2LSB below AGND. The trim procedures for both cases are as follows. (See Figure 14.)

Last Code Transition Adjust

Apply a voltage of 4.99634 volts (FS/2 – 3/2LSBs) at V_{IN}. Adjust R5 until the ADC output code flickers between 1111 1111 1110 and 1111 1111 1111.

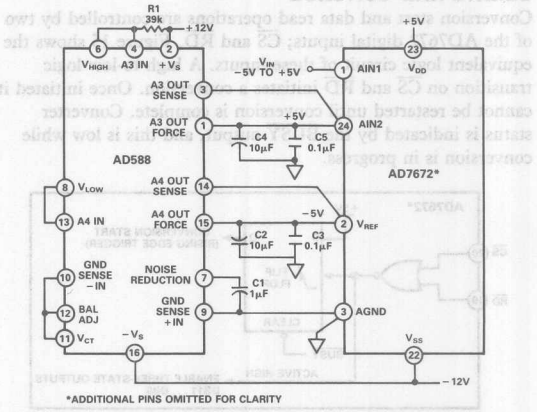

Figure 12. Bipolar Operation Using an AD588 Voltage Reference

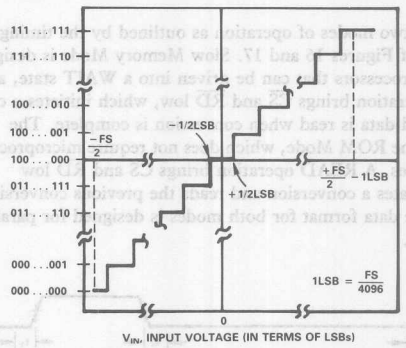

Figure 13. Ideal Input/Output Transfer Characteristic for Bipolar Operation

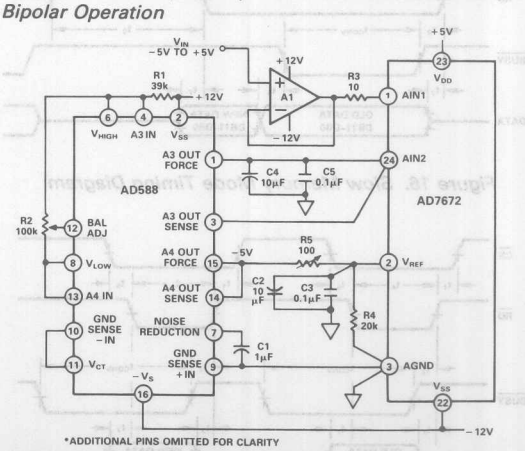

Figure 14. Bipolar Operation with Offset and Gain Error Adjust

Bipolar Zero Error Adjust

Apply a voltage of −1.22mV at V_{IN} and adjust R5 until the ADC output code flickers between 0111 1111 1111 and 1000 0000 0000.

of the AD7672 digital inputs; $\overline{CS}$ and $\overline{RD}$. Figure 15 shows the equivalent logic circuit of these inputs. A high-to-low logic transition on $\overline{CS}$ and $\overline{RD}$ initiates a conversion. Once initiated it cannot be restarted until conversion is complete. Converter status is indicated by the $\overline{BUSY}$ output, and this is low while conversion is in progress.

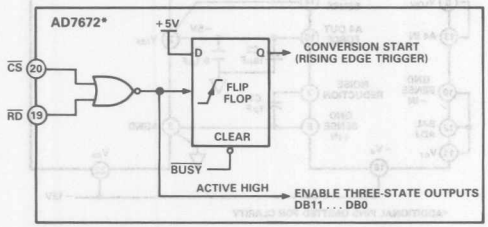

Figure 15. Internal Logic for Control Inputs $\overline{CS}$ and $\overline{RD}$

There are two modes of operation as outlined by the timing diagrams of Figures 16 and 17. Slow Memory Mode is designed for microprocessors that can be driven into a WAIT state, a READ operation brings $\overline{CS}$ and $\overline{RD}$ low, which initiates a conversion and data is read when conversion is complete. The second is the ROM Mode, which does not require microprocessor WAIT states. A READ operation brings $\overline{CS}$ and $\overline{RD}$ low which initiates a conversion and reads the previous conversion result. The data format for both modes is designed for parallel interfacing.

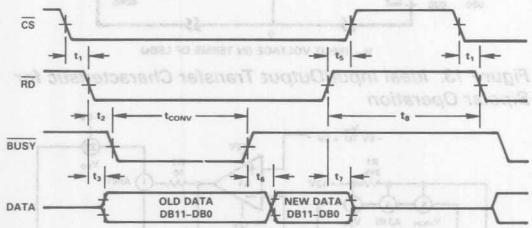

Figure 16. Slow Memory Mode Timing Diagram

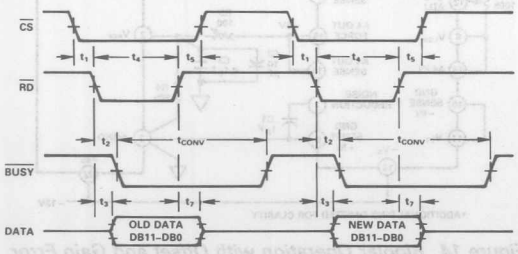

Figure 17. ROM Mode Timing Diagram

$\overline{CS}$ and $\overline{RD}$ going low triggers a conversion and the AD7672 acknowledges by taking $\overline{BUSY}$ low. Data from the previous conversion appears on the three-state data outputs. $\overline{BUSY}$ returns high at the end of conversion when the output latches have been updated and the conversion result is placed on the output data bus.

ROM MODE

The ROM Mode avoids placing a microprocessor into a wait state. A conversion is started with a READ operation and the 12-bits of data from the previous conversion are available on the data outputs while $\overline{CS}$ and $\overline{RD}$ are low. This data may be disregarded if not required. A second READ operation reads the new data and starts another conversion. A delay at least as long as the AD7672 conversion time must be allowed between READ operations.

MICROPROCESSOR INTERFACING

The AD7672 is designed to interface to microprocessors as a memory mapped device. The $\overline{CS}$ and $\overline{RD}$ inputs are common control inputs to all peripheral memory interfacing.

MC68000 MICROPROCESSOR

Figure 18 shows a typical interface for the MC68000. The AD7672 is operating in the Slow Memory Mode. Assuming the AD7672 is located at address C000 then the following single 16-bit MOVE instruction both starts a conversion and reads the conversion result.

Move.W $C000,D0

At the beginning of the instruction cycle when the ADC address is selected, $\overline{BUSY}$ and $\overline{CS}$ assert $\overline{DTACK}$, so that the 68000 is forced into a WAIT state. At the end of conversion $\overline{BUSY}$ returns high and the conversion result is placed in the D0 register of the UP.

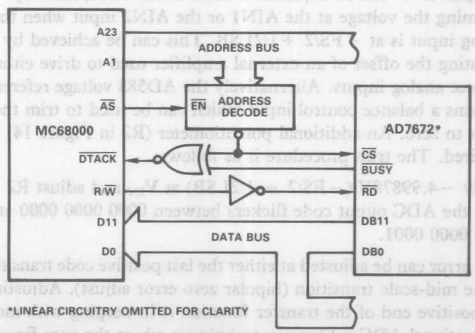

Figure 18. AD7672 –MC68000 Interface

The AD7672 is operating in the Slow Memory Mode and a two byte read is required. Not shown in the Figure is the 8-bit latch required to demultiplex the 8085A common address/data bus. The following LOAD instruction starts a conversion and reads the conversion result into the HL register pair.

For the 8085A	LHLD (B000)
For the Z-80	LDHL (B000)

This is a two byte read instruction. During the first read operation, $\overline{BUSY}$ forces the microprocessor to wait for the AD7672 conversion. At the end of conversion the low byte (DB7-DB0) is loaded into the HL register pair and the high byte (DB11-DB8) is latched into a 74HC374. No WAIT states are inserted during the second read operation when the microprocessor is reading the high data byte.

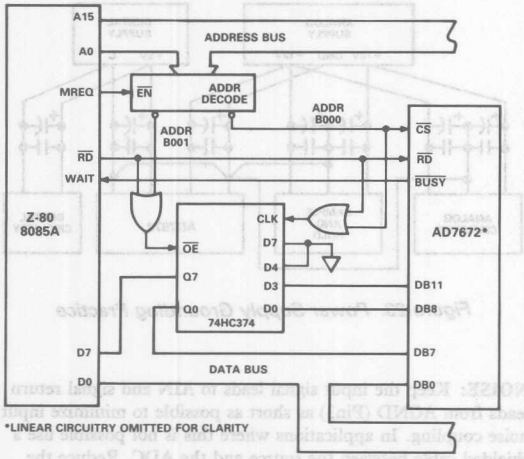

Figure 19. AD7672 – 8085A/Z80 Interface

IBM PC* COMPUTER

The −12V power supply operation of the AD7672 makes it an ideal choice for the IBM PC. A typical interface is shown in Figure 20. The AD7672 is configured in the ROM mode. Two addresses are required to read the 12-bit ADC data over the 8-bit data bus. An I/O read instruction to the ADC address (B000) starts a conversion and reads the low data byte (DB7-DB0). This data is from the previous conversion. The high byte (DB11-DB8) may be read with a similar I/O instruction to the 74HC374 latch (address B001). Alternatively the up-to-date data may be read at the end of conversion. The AD7672 $\overline{BUSY}$ may be used to interrupt the IBM PC as shown in Figure 20. The data is then read with two I/O instructions as before. Note a read instruction to the ADC should not be attempted while conversion is in progress.

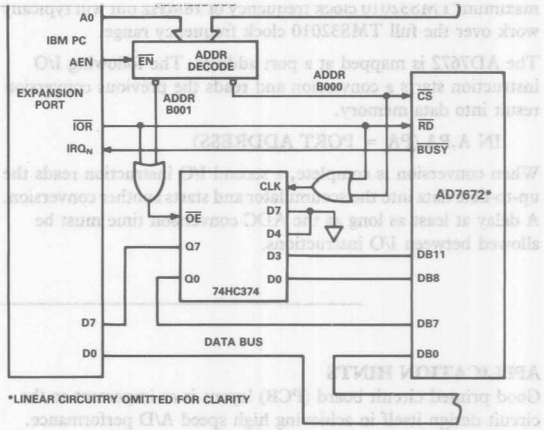

Figure 20. AD7672 – IBM PC Interface

ADSP-2100 DIGITAL SIGNAL PROCESSOR

The ADSP-2100 like other digital signal processors requires very fast data access times beyond the capabilities of the AD7672. This problem is easily overcome by inserting 74HC374 latches in the data bus as in Figure 21. Again for this interface a single instruction is sufficient to read the AD7672 conversion result.

MRO = DM (ADC ADDRESS)

This instruction initiates a conversion and reads the previous conversion result into the MRO register. $\overline{CS}$ and $\overline{RD}$ are gated so that they remain low for the duration of the conversion. Note that no WAIT states are inserted even though the AD7672 is configured for a Slow Memory mode. At the end of conversion, $\overline{BUSY}$ going high latches the new result into the 74HC374 latches. An RC delay is inserted to compensate for the data setup time after $\overline{BUSY}$ (t_6).

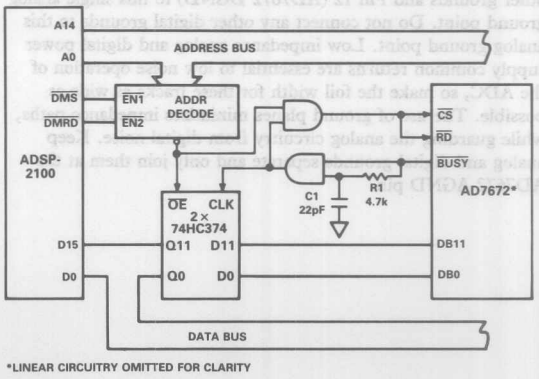

Figure 21. AD7672 – ADSP-2100 Interface

TMS32010 MICROCOMPUTER

Figure 22 shows an AD7672-TMS32010 interface. The AD7672 is operating in the ROM mode. The interface is designed for a maximum TMS32010 clock frequency of 18MHz but will typically work over the full TMS32010 clock frequency range.

The AD7672 is mapped at a port address. The following I/O instruction starts a conversion and reads the previous conversion result into data memory.

IN A,PA (PA = PORT ADDRESS)

When conversion is complete, a second I/O instruction reads the up-to-date data into the accumulator and starts another conversion. A delay at least as long as the ADC conversion time must be allowed between I/O instructions.

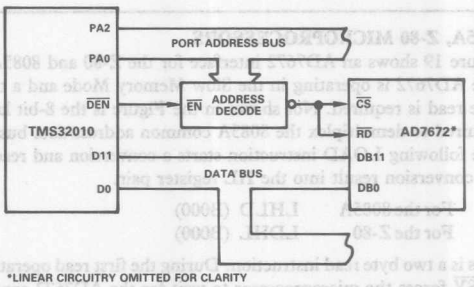

Figure 22. AD7672 – TMS32010 Interface

APPLICATION HINTS

Good printed circuit board (PCB) layout is as important as the circuit design itself in achieving high speed A/D performance. For 12-bit performance the AD7672's comparator is required to make bit decisions to an accuracy of 0.61mV. To achieve this, the designer has to be conscious of noise both in the ADC itself and the preceding analog circuitry. Switching mode power supplies are not recommended as the switching spikes will feed through to the comparator causing noisy code transitions. Other causes of concern are ground loops and digital feedthrough from microprocessors. These are factors which influence any ADC, and a proper PCB layout which minimizes these effects is essential for best performance.

LAYOUT HINTS

Ensure that the layout for the printed circuit board has the digital and analog signal lines separated as much as possible. Take care not to run any digital track alongside an analog signal track. Guard (screen) the analog input with AGND.

Establish a single point analog ground (star ground) separate from the logic system ground at Pin 3 (AGND) or as close as possible to the AD7672 as shown in Figure 23. Connect all other grounds and Pin 12 (AD7672 DGND) to this single analog ground point. Do not connect any other digital grounds to this analog ground point. Low impedance analog and digital power supply common returns are essential to low noise operation of the ADC, so make the foil width for these tracks as wide as possible. The use of ground planes minimizes impedance paths, while guarding the analog circuitry from digital noise. Keep analog and digital grounds separate and only join them at the AD7672 AGND pin.

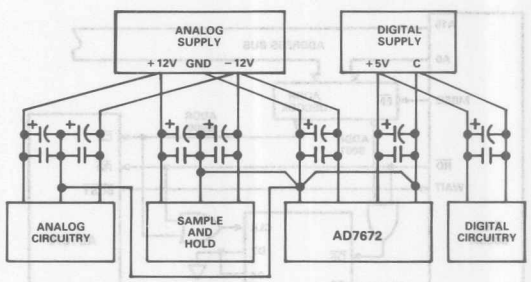

Figure 23. Power Supply Grounding Practice

NOISE: Keep the input signal leads to AIN and signal return leads from AGND (Pin3) as short as possible to minimize input noise coupling. In applications where this is not possible use a shielded cable between the source and the ADC. Reduce the ground circuit impedance as much as possible, since any potential difference in grounds between the signal source and the ADC appears as an error voltage in series with the input signal.

Microprocessor applications generate noisy environments, making 12-bit performance difficult to achieve, especially when the ADC is connected to a continously active bus. The problem can be eliminated by forcing the microprocessor into a WAIT state during conversion (see Slow Memory Mode interfacing), or by using three-state buffers to isolate the AD7672 data bus.

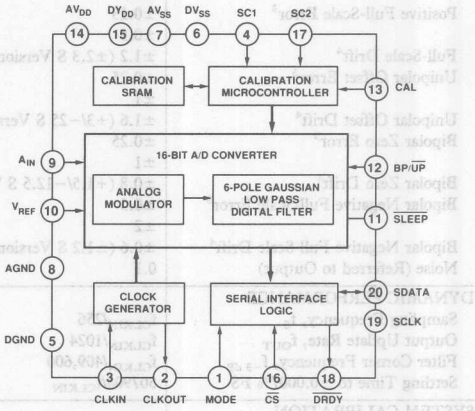
LC²MOS 16-Bit A/D Converter

AD7701

FEATURES
- Monolithic 16-Bit ADC
- 0.0015% Linearity Error
- On-Chip Self-Calibration Circuitry
- Programmable Low Pass Filter
  - 0.1 Hz to 10 Hz Corner Frequency
- 0 to +2.5 V or ±2.5 V Analog Input Range
- 4 kSPS Output Data Rate
- Flexible Serial Interface
- Ultralow Power

APPLICATIONS
- Industrial Process Control
- Weigh Scales
- Portable Instrumentation
- Remote Data Acquisition

GENERAL DESCRIPTION



The AD7701 is a 16-bit ADC which uses a sigma delta conversion technique. The analog input is continuously sampled by an analog modulator whose mean output duty cycle is proportional to the input signal. The modulator output is processed by an on-chip digital filter with a six-pole Gaussian response, which updates the output data register with 16-bit binary words at word rates up to 4 kHz. The sampling rate, filter corner frequency and output word rate are set by a master clock input that may be supplied externally, or by a crystal-controlled on-chip clock oscillator.

The inherent linearity of the ADC is excellent, and end-point accuracy is ensured by self-calibration of zero and full-scale which may be initiated at any time. The self-calibration scheme can also be extended to null system offset and gain errors in the input channel.

The output data is accessed through a flexible serial port, which has an asynchronous mode compatible with UARTs and two synchronous modes suitable for interfacing to shift registers or the serial ports of industry-standard microcontrollers.

CMOS construction insures low power dissipation, and a power down mode reduces the idle power consumption to only 10 μW.

FUNCTIONAL BLOCK DIAGRAM

PRODUCT HIGHLIGHTS

1. The AD7701 offers 16-bit resolution coupled with outstanding 0.0015% accuracy.
2. No missing codes ensures true, usable, 16-bit dynamic range, removing the need for programmable gain and level-setting circuitry.
3. The effects of temperature drift are eliminated by on-chip self-calibration, which removes zero and gain error. External circuits can also be included in the calibration loop to remove system offsets and gain errors.
4. A flexible synchronous/asynchronous interface allows the AD7701 to interface directly to UARTs or to the serial ports of industry-standard microcontrollers.
5. Low operating power consumption and an ultralow power standby mode make the AD7701 ideal for loop-powered remote sensing applications, or battery-powered portable instruments.

AD7701—SPECIFICATIONS

(T_A = +25°C; AV_{DD} = DV_{DD} = +5 V; AV_{SS} = DV_{SS} = −5 V; V_{REF} = +2.5 V; f_{CLKIN} = 4.096 MHz; Bipolar Mode; MODE = +5 V; A_{IN} Source Resistance = 750 Ω[1] with 1 nF to AGND at A_{IN}, unless otherwise stated.)

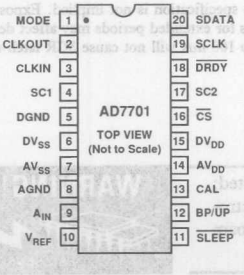
NOTES
[1]The A_{IN} pin presents a very high impedance dynamic load which varies with clock frequency.
[2]Temperature ranges are as follows: A, B Versions; −40°C to +85°C; S, T Versions; −55°C to +125°C.
[3]Apply after calibration at the temperature of interest. Full-scale error applies for both unipolar and bipolar input ranges.
[4]Total drift over the specified temperature range since calibration at power-up at +25°C. This is guaranteed by design and/or characterization. Recalibration at any temperature will remove these errors.
[5]In unipolar mode the offset can have a negative value ($-V_{REF}$) such that the unipolar mode can mimic bipolar mode operation.
[6]The specifications for input overrange and for input span apply additional constraints on the offset calibration range.
[7]For unipolar mode, input span is the difference between full-scale and zero scale. Fir bipolar mode, input span is the difference between positive and negative full-scale points. When using less than the maximum input span, the span range may be placed anywhere within the range of $\pm(V_{REF} + 0.1)$.
[8]All digital outputs unloaded. All digital inputs at 5 V CMOS levels.
[9]Applies in 0.1 Hz to 10 Hz bandwidth. PSRR at 60 Hz will exceed 120 dB due to the digital filter.
[10]CLKIN is stopped. All digital inputs are grounded.
Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS[1]
(T_A = +25°C unless otherwise noted)

DV_{DD} to AGND . . . . . −0.3 V to +6 V
DV_{DD} to AV_{DD} . . . . . −0.3 V to +0.3 V
DV_{SS} to AGND . . . . . +0.3 V to −6 V
AV_{DD} to AGND . . . . . −0.3 V to +6 V
AV_{SS} to AGND . . . . . +0.3 V to −6 V
AGND to DGND . . . . . −0.3 V to +0.3 V
Digital Input Voltage to DGND . . . −0.3 V to DV_{DD} +0.3 V
Analog Input
Voltage to AGND . . . . . AV_{SS} −0.3 V to AV_{DD} +0.3 V
Input Current to Any Pin Except Supplies[2] . . . . . ±10 mA
Operating Temperature Range
Commercial Plastic (A, B Versions) . . . . . −40°C to +85°C
Industrial Cerdip (A, B Versions) . . . . . −40°C to +85°C
Extended Cerdip (S, T Version) . . . . . −55°C to +125°C
Storage Temperature Range . . . . . −65°C to +150°C
Lead Temperature (Soldering, 10 secs) . . . . . +300°C
Power Dissipation (Any Package) to +75°C . . . . . 450 mW
Derates above +75°C by . . . . . 10 mW/°C

NOTES
[1]Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
[2]Transient currents of up to 100 mA will not cause SCR latch-up.

CAUTION



ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

PIN FUNCTION DESCRIPTION

Pin	Mnemonic	Description
1	MODE	Selects the Serial Interface Mode. If MODE is tied to −5 V, the AD7701 will operate in the asynchronous communications (AC) mode. The SCLK pin is configured as an input, and data is transmitted in two bytes, each with one start bit and two stop bits. If MODE is tied to DGND, the synchronous external clocking (SEC) mode is selected. SCLK is configured as an input, and the output appears without formatting, the MSB coming first. If MODE is tied to +5 V, the AD7701 operates in the synchronous self-clocking (SSC) mode. SCLK is configured as an output, with a clock frequency of $f_{CLKIN}/4$ and 25% duty-cycle.
2	CLKOUT	Clock Output to generate an Internal Master Clock by connecting a crystal between CLKOUT and CLKIN. If an external clock is used, CLKOUT is not connected.
3	CLKIN	Clock Input for External Clock.
4, 17	SC1, SC2	System Calibration Pins. The state of these pins, when CAL is taken high, determines the type of calibration performed.
5	DGND	Digital Ground. Ground reference for all digital signals.
6	DV_{SS}	Digital Negative Supply, −5 V nominal.
7	AV_{SS}	Analog Negative Supply, −5 V nominal.
8	AGND	Analog Ground. Ground reference for all analog signals.
9	A_{IN}	Analog Input.
10	V_{REF}	Voltage Reference Input, +2.5 V nominal. This determines the value of positive full-scale in the unipolar mode and of both positive and negative full-scale in the bipolar mode.
11	$\overline{SLEEP}$	Sleep mode pin. When this pin is taken low, the AD7701 goes into a low-power mode with typically 10 μW power consumption.
12	BP/$\overline{UP}$	Bipolar/Unipolar Mode Pin. When this pin is low, the AD7701 is configured for a unipolar input range going from AGND to V_{REF}. When Pin 12 is high, the AD7701 is configured for a bipolar input range, $\pm V_{REF}$.
13	CAL	Calibration Mode Pin. When CAL is taken high for more than 4 cycles, the AD7701 is reset and performs a calibration cycle when CAL is brought low again. The CAL pin can also be used as a strobe to synchronize the operation of several AD7701s.
14	AV_{DD}	Analog Positive Supply, +5 V nominal.
15	DV_{DD}	Digital Positive Supply, +5 V nominal.
16	$\overline{CS}$	Chip Select Input. When $\overline{CS}$ is brought low, the AD7701 will begin to transmit serial data in a format determined by the state of the MODE pin.
18	$\overline{DRDY}$	Data Ready output. $\overline{DRDY}$ is low when valid data is available in the output register. It goes high after transmission of a word is completed. It also goes high for four clock cycles when a new data word is being loaded into the output register, to indicate that valid data is not available, irrespective of whether data transmission is complete or not.
19	SCLK	Serial Clock Input/Output. The SCLK pin in configured as an input or output, dependent on the type of serial data transmission that has been selected by the MODE pin. When configured as an output in the synchronous self-clocking mode, it has a frequency of $f_{CLKIN}/4$ and a duty cycle of 25%.
20	SDATA	Serial Data Output. The AD7701's output data is available at this pin as a 16-bit serial word. The transmission format is determined by the state of the MODE pin.

t_{17}	40	40	ns max	$\overline{CS}$ Setup Time. Typically 20 ns
t_{18}	180	180	ns max	Data Delay Time. Typically 90 ns
t_{19}	200	200	ns max	SCLK Falling Edge to Hi-Z Delay. Typically 100 ns

NOTES

[1]Sample tested at +25°C to ensure compliance. All input signals are specified with $t_r = t_f$ = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

[2]See Figures 1 to 5.

[3]CLKIN Duty Cycle range is 20% to 80%. CLKIN must be supplied whenever the AD7701 is not in SLEEP mode. If no clock is present in this case, the device can draw higher current than specified and possibly become uncalibrated.

[4]The AD7701 is production tested with f_{CLKIN} at 4.096 MHz. It is guaranteed by characterization to operate at 200 kHz.

[5]Specified using 10% and 90% points on waveform of interest.

[6]In order to synchronize several AD7701s together using the $\overline{SLEEP}$ pin, this specification is met.

[7]t_4 and t_{13} are measured with the load circuit of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.

[8]t_8, t_{10}, t_{15} and t_{16} are derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove the effects of charging or discharging the 100 pF capacitor. This means that the time quoted in the Timing Characteristics is the true bus relinquish time of the part and as such is independent of external bus loading capacitance.

[9]If $\overline{CS}$ is returned high before all 16 bits are output, the SDATA and SCLK outputs will complete the current data bit and then go to high impedance.

[10]If $\overline{CS}$ is activated asynchronously to $\overline{DRDY}$, $\overline{CS}$ will not be recognized if it occurs when $\overline{DRDY}$ is high for four clock cycles. The propagation delay time may be as great as 4 CLKIN cycles plus 160 ns. To guarantee proper clocking of SDATA when using asynchronous $\overline{CS}$, the SCLK input should not be taken high sooner then 4 CLKIN cycles plus 160 ns after $\overline{CS}$ goes low.

[11]SDATA is clocked out on the falling edge of the SCLK input.

TERMINOLOGY

LINEARITY ERROR
This is the maximum deviation of any code from a straight line passing through the endpoints of the transfer function. The endpoints of the transfer function are Zero-Scale (not to be confused with Bipolar Zero), a point 0.5 LSB below the first code transition (000 . . . 000 to 000 . . . 001) and Full-Scale, a point 1.5 LSB above the last code transition (111 . . . 110 to 111 . . . 111). The error is expressed as a percentage of full scale.

DIFFERENTIAL LINEARITY ERROR
This is the difference between any code's actual width and the ideal (1 LSB) width. Differential Linearity Error is expressed in LSBs. A differential linearity specification of ±1 LSB or less guarantees monotonicity.

POSITIVE FULL-SCALE ERROR
Positive Full-Scale Error is the deviation of the last code transition (111 . . . 110 to 111 . . . 111) from the ideal (V_{REF} −3/2 LSBs). It applies to both positive and negative analog input ranges and it is expressed in microvolts.

UNIPOLAR OFFSET ERROR
Unipolar Offset Error is the deviation of the first code transition from the ideal (AGND + 0.5 LSB) when operating in the unipolar mode. It is expressed in microvolts.

BIPOLAR ZERO ERROR
This is the deviation of the mid-scale transition (0111 . . . 111 to 1000 . . . 000) from the ideal (AGND − 0.5 LSB) when operating in the bipolar mode. It is expressed in microvolts.

BIPOLAR NEGATIVE FULL-SCALE ERROR
This is the deviation of the first code transition from the ideal ($-V_{REF}$ + 0.5 LSB), when operating in the bipolar mode. It is expressed in microvolts.

POSITIVE FULL-SCALE OVERRANGE
Positive Full-Scale Overrange is the amount of overhead available to handle input voltages greater than $+V_{REF}$ (for example, noise peaks or excess voltages due to system gain errors in system calibration routines) without introducing errors due to overloading the analog modulator or overflowing the digital filter. It is expressed in millivolts.

NEGATIVE FULL-SCALE OVERRANGE
This is the amount of overhead available to handle voltages below $-V_{REF}$ without overloading the analog modulator or overflowing the digital filter. Note that the analog input will accept negative voltage peaks even in the unipolar mode. The overhead is expressed in millivolts.

In the system calibration modes (SC2 low) the AD7701 calibrates its offset with respect to the A_{IN} pin. The Offset Calibration Range specification defines the range of voltages, expressed as a percentage of V_{REF} that the AD7701 can accept and still calibrate offset accurately.

FULL-SCALE CALIBRATION RANGE

This is the range of voltages that the AD7701 can accept in the system calibration mode and still calibrate full-scale correctly.

INPUT SPAN

In system calibration schemes, two voltages applied in sequence to the AD7701's analog input define the analog input range. The input span specification defines the minimum and maximum input voltages from zero to full-scale that the AD7701 can accept and still calibrate gain accurately. The input span is expressed as a percentage of V_{REF}.

GENERAL DESCRIPTION

The AD7701 is a 16-bit A/D converter with on-chip digital filtering, intended for the measurement of wide dynamic range, low frequency signals such as those representing chemical, physical or biological processes. It contains a charge-balancing (sigma-delta) ADC, calibration microcontroller with on-chip static RAM, a clock oscillator and a serial communications port.

The analog input signal to the AD7701 is continuously sampled at a rate determined by the frequency of the master clock, CLKIN. A charge-balancing A/D converter (Sigma Delta Modulator) converts the sampled signal into a digital pulse train whose duty cycle contains the digital information. A six-pole Gaussian digital low-pass filter processes the output of the modulator and updates the 16-bit output register at a 4 kHz rate. The output data can be read from the serial port randomly or periodically at any rate up to 4 kHz.

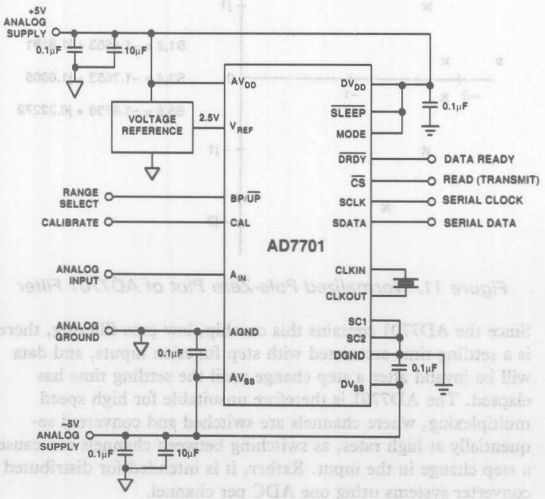

Figure 7. Typical System Connection Diagram

bration microcontroller and SRAM to store calibration parameters. A calibration cycle may be initiated at any time using the CAL control input.

Other system components may also be included in the calibration loop to remove offset and gain errors in the input channel.

For battery operation, the AD7701 also offers a standby mode that reduces idle power consumption to typically 10 μW.

THEORY OF OPERATION

The general block diagram of a sigma delta ADC is shown in Figure 8. It contains the following elements.

1. A sample-hold amplifier.
2. A differential amplifier or subtractor.
3. An analog low pass filter.
4. A 1-bit A/D converter (comparator).
5. A 1-bit DAC.
6. A digital low pass filter.

In operation, the analog signal sample is fed to the subtractor, along with the output of the 1-bit DAC. The filtered difference signal is fed to the comparator, whose output samples the difference signal at a frequency many times that of the analog signal sampling frequency (oversampling).

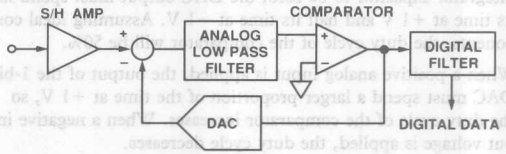

Figure 8. General Sigma Delta ADC

Oversampling is fundamental to the operation of sigma delta ADCs. Using the quantization noise formula for an ADC:

$$SNR = (6.02 \times number\ of\ bits + 1.76)\ dB$$

a 1-bit ADC or comparator yields an SNR of 7.78 dB.

The AD7701 samples the input signal at 16 kHz, which spreads the quantization noise from 0 to 8 kHz. Since the specified analog input bandwidth of the AD7701 is only 0 to 10 Hz, the noise energy in this bandwidth would be only 1/800 of the total quantization noise, even if the noise energy was spread evenly throughout the spectrum. It is reduced still further by analog filtering in the modulator loop, which shapes the quantization noise spectrum to move most of the noise energy to frequencies above 10 Hz. The SNR performance in the 0 to 10 Hz range is conditioned to the 16-bit level in this fashion.

The output of the comparator provides the digital input for the 1-bit DAC, so that the system functions as a negative feedback loop that tries to minimize the difference signal. The digital data that represents the analog input voltage is contained in the duty cycle of the pulse train appearing at the output of the comparator. It can be retrieved as a parallel binary data word using a digital filter.

lowpass filter or integrator. It also illustrates the derivation of the alternative name for these devices: Charge-Balancing ADCs.

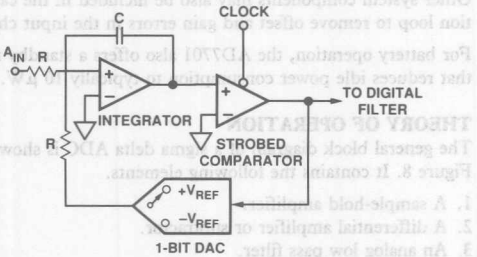

Figure 9. Basic Charge-Balancing ADC

The term charge-balancing comes from the fact that this system is a negative feedback loop that tries to keep the net charge on the integrator capacitor at zero, by balancing charge injected by the input voltage with charge injected by the 1-bit DAC. When the analog input is zero, the only contribution to the integrator output comes from the 1-bit DAC. For the net charge on the integrator capacitor to be zero, the DAC output must spend half its time at +1 V and half its time at −1 V. Assuming ideal components, the duty cycle of the comparator will be 50%.

When a positive analog input is applied, the output of the 1-bit DAC must spend a larger proportion of the time at +1 V, so the duty cycle of the comparator increases. When a negative input voltage is applied, the duty cycle decreases.

The AD7701 uses a second-order sigma delta modulator and a sophisticated digital filter that provides a rolling average of the sampled output. After power-up or if there is a step change in the input voltage, there is a settling time that must elapse before valid data is obtained.

DIGITAL FILTERING

The AD7701's digital filter behaves like a similar analog filter, with a few minor differences.

First, since digital filtering occurs after the A to D conversion process, it can remove noise injected during the conversion process. Analog filtering cannot do this.

On the other hand, analog filtering can remove noise superimposed on the analog signal before it reaches the ADC. Digital filtering cannot do this and noise peaks riding on signals near full scale have the potential to saturate the analog modulator and digital filter, even though the average value of the signal is within limits. To alleviate this problem, the AD7701 has overrange headroom built into the sigma delta modulator and digital filter which allows overrange excursions of 100 mV. If noise signals are larger than this, consideration should be given to analog input filtering, or to reducing the gain in the input channel so that a full-scale input (2.5 V) gives only a half-scale input to the AD7701 (1.25 V). This will provide an overrange capability greater than 100% at the expense of reducing the dynamic range by 1 bit (50%).

FILTER CHARACTERISTICS

The cutoff frequency of the digital filter is $f_{CLK}/409600$. At the Gaussian response that provides 55 dB of 60 Hz rejection for a 10 Hz cutoff frequency. If the clock frequency is halved to give a 5 Hz cutoff, 60 Hz rejection is better than 90 dB. A normalized s-domain pole-zero plot of the filter is shown in Figure 11.

The response of the filter is defined by:

$$H(x)=[1 + 0.693x^2 + 0.240x^4 + 0.0555x^6 + 0.00962x^8 + 0.00133x^{10} + 0.000154x^{12}]^{-0.5}$$

where:

$x = f/f_{3\,dB}$, $f_{3\,dB} = f_{CLKIN}/409600$,

and

f is the frequency of interest.

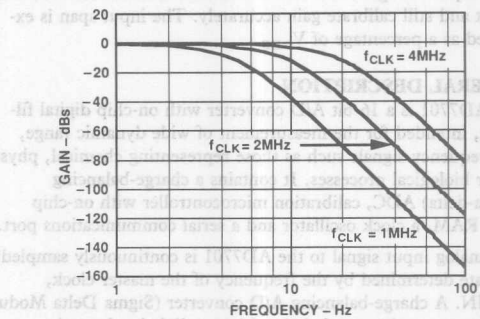

Figure 10. Frequency Response of AD7701 Filter

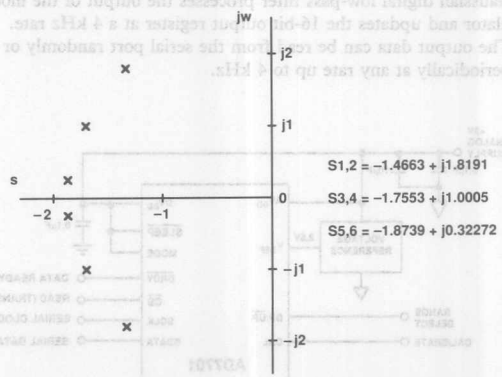

Figure 11. Normalized Pole-Zero Plot of AD7701 Filter

Since the AD7701 contains this on-chip, low pass filtering, there is a settling time associated with step function inputs, and data will be invalid after a step change until the settling time has elapsed. The AD7701 is therefore unsuitable for high speed multiplexing, where channels are switched and converted sequentially at high rates, as switching between channels can cause a step change in the input. Rather, it is intended for distributed converter systems using one ADC per channel.

However, slow multiplexing of the AD7701 is possible, provided that the settling time is allowed to elapse before data for the new channel is accessed.

The output settling of the AD7701 in response to a step input change is shown in Figure 12. The Gaussian response has fast settling with no overshoot, and the worst-case settling time to ±0.0007% (±0.5 LSB) is 125 ms with a 4.096 MHz master clock frequency.

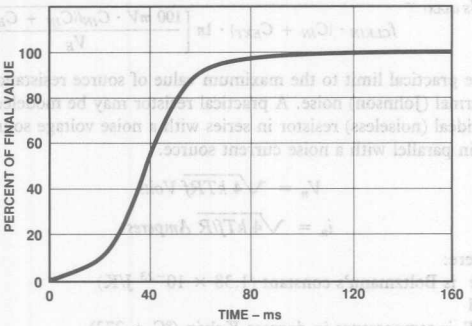

Figure 12. AD7701 Step Response

USING THE AD7701

SYSTEM DESIGN CONSIDERATIONS

The AD7701 operates differently from successive approximation ADCs or other integrating ADCs. Since it samples the signal continuously, like a tracking ADC, there is no need for a start convert command. The 16-bit output register is updated at a 4 kHz rate, and the output can be read at any time, either synchronously or asynchronously.

CLOCKING

The AD7701 requires a master clock input, which may be an external TTL/CMOS compatible clock signal applied to the CLKIN pin (CLKOUT not used). Alternatively, a crystal of the correct frequency can be connected between CLKIN and CLKOUT, when the clock circuit will function as a crystal-controlled oscillator.

The input sampling frequency, output data rate, filter characteristics and calibration time are all directly related to the master clock frequency f_{CLKIN} by the ratios given in the specification table. Therefore, the first step in system design with the AD7701 is to select a master clock frequency suitable for the bandwidth and output data rate required by the application.

ANALOG INPUT RANGES

The AD7701 performs conversion relative to an externally supplied reference voltage, which allows easy interfacing to ratiometric systems. In addition, either unipolar or bipolar input voltage range may be selected using the BP/$\overline{UP}$ input. With BP/$\overline{UP}$ tied low, the input range is unipolar and the span is 0 to $+V_{REF}$. With BP/$\overline{UP}$ tied high, the input range is bipolar and the span is $\pm V_{REF}$. In the bipolar mode both positive and negative full-scale are directly determined by V_{REF}. This offers superior tracking of positive and negative full scale and better midscale (bipolar zero) stability than bipolar schemes that simply scale and offset the input range.

The digital output coding for the unipolar range is Unipolar Binary; for the bipolar range it is Offset Binary. Bit weights for the unipolar and bipolar modes are shown in Table I. The input voltages and output codes for unipolar and bipolar ranges, using the recommended +2.5 V reference, are shown in Table II.

	Unipolar Mode			Bipolar Mode		
μV	LSBs	% FS	ppm FS	LSBs	% FS	ppm FS
10	0.26	0.0004	4	0.13	0.0002	2
19	0.5	0.0008	8	0.26	0.0004	4
38	1.00	0.0015	15	0.5	0.0008	8
76	2.00	0.0031	31	1.00	0.0015	15
153	4.00	0.0061	61	2.00	0.0031	31

Table I. Bit Weight Table (2.5 V Reference Voltage)

Unipolar Mode Input Relative to FS and AGND	Input in Volts	Bipolar Mode Input Relative to FS and AGND	Input in Volts	Output Data
$+V_{REF}$ −1.5 LSB	+2.499943	$+V_{REF}$ −1.5 LSB	+2.499886	1111 1111 1111 1111

[4]Bipolar Mode, 1 LSB = 5 V/65536 = 0.000076 V
[5]Inputs are voltages at code transitions.

Table II. Output Coding

INPUT SIGNAL CONDITIONING

Reference voltages from +1 V to +3 V may be used with the AD7701, with little degradation in performance. Input ranges that cannot be accommodated by this range of reference voltages may be achieved by input signal conditioning. This may take the form of gain to accommodate a smaller signal range, or passive attenuation to reduce a larger input voltage range.

Source Resistance

If passive attenuators are used in front of the AD7701, care must be taken to ensure that the source impedance is sufficiently low. The AD7701 has an analog input with over 1 GΩ dc input resistance. In parallel with this there as a small dynamic load which varies with the clock frequency (see Figure 13). Each time the analog input is sampled, a 10 pF capacitor draws a charge packet of maximum 1 pC (10 pF × 100 mV)

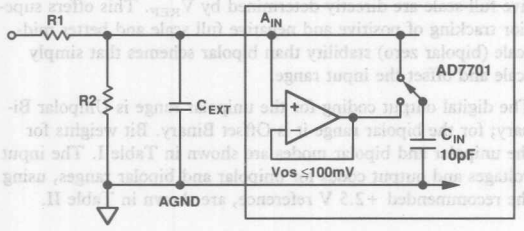

Figure 13. Equivalent Input Circuit and Input Attenuator

from the analog source with a frequency $f_{CLKIN}/256$. For a 4.096 MHz CLKIN, this yields an average current draw of 16 nA. After each sample the AD7701 allows 62 clock periods for the input voltage to settle. The equation which defines settling time is:

$$V_O = V_{IN}\,[1 - e^{-t/RC}]$$

where:

V_O is the final settled value,
V_{IN} is the value of the input signal,
R is the value of the input source resistance,
C is the 10 pF sample capacitor,
t is equal to $62/f_{CLKIN}$.

From this, the following equation can be developed which gives the maximum allowable source resistance, $R_{S(MAX)}$, for an error of V_E:

$$R_{S\,(MAX)} = \frac{62}{f_{CLKIN} \cdot (10\,pF) \cdot 1n\,(100\,mV/V_E)}$$

Provided the source resistance is less than this value, the analog input will settle within the desired error band in the requisite 62 clock periods. Insufficient settling leads to offset errors. These can be calibrated in system calibration schemes.

If a limit of 10 μV (0.25 LSB at 16 bits) is set for the maximum offset voltage, then the maximum allowable source resistance is 160 kΩ from the above equation, assuming that there is no external stray capacitance.

An RC filter may be added in front of the AD7701 to reduce high frequency noise. With an external capacitor added from A_{IN} to AGND, the following equation will specify the maximum allowable source resistance:

$$R_{S\,(MAX)} = \frac{62}{f_{CLKIN} \cdot (C_{IN} + C_{EXT}) \cdot 1n\left[\frac{100\,mV \cdot C_{IN}/(C_{IN} + C_{EXT})}{V_E}\right]}$$

The practical limit to the maximum value of source resistance is thermal (Johnson) noise. A practical resistor may be modeled as an ideal (noiseless) resistor in series with a noise voltage source or in parallel with a noise current source.

$$V_n = \sqrt{4\,kTRf}\ Volts$$

$$i_n = \sqrt{4\,kTf/R}\ Amperes$$

where:

k is Boltzmann's constant (1.38×10^{-23} J/K)
and
T is temperature in degrees Kelvin (°C + 273).

Active signal conditioning circuits such as op amps generally do not suffer from problems of high source impedance. Their open-loop output resistance is normally only tens of ohms and, in any case, most modern general purpose op amps have sufficiently fast closed-loop settling time for this not to be a problem. Offset voltage in op amps can be eliminated in a system calibration routine. With the wide dynamic range and small LSB size of the AD7701, noise can also be a problem, but the digital filter will reject most broadband noise above its cutoff frequency. However, in certain applications there may be a need for analog input filtering.

Antialias Considerations

The digital filter of the AD7701 does not provide any rejection at integer multiples of the sampling frequency ($nf_{CLKIN}/256$, where n = 1, 2, 3 . . .) .

With a 4.096 MHz master clock there are narrow (±10 Hz) bands at 16 kHz, 32 kHz, 48 kHz, etc., where noise passes unattenuated to the output.

However, due to the AD7701's high oversampling ratio of 800 (16 kHz to 20 Hz) these bands occupy only a small fraction of the spectrum, and most broadband noise is filtered.

The reduction in broadband noise is given by:

$$e_{OUT} = e_{IN}\sqrt{2f_C/f_S} = 0.035\,e_{IN}$$

where:

e_{IN} and e_{OUT} are rms noise terms referred to the input
f_C is the filter −3 dB corner frequency ($f_{CLKIN}/409600$)
and
f_S is the sampling frequency ($f_{CLKIN}/256$).

Since the ratio of f_S to f_{CLKIN} is fixed, the digital filter reduces broadband white noise by 96.5% independent of the master clock frequency.

VOLTAGE REFERENCE CONNECTIONS

The voltage applied to the V_{REF} pin defines the analog input range. The specified reference voltage is 2.5 V, but the AD7701 will operate with reference voltages from 1 V to 3 V with little degradation in performance.

The reference input presents exactly the same dynamic load as the analog input, but in the case of the reference input, source resistance and long settling time introduce gain errors rather than offset errors. Fortunately, most precision references have sufficiently low output impedance and wide enough bandwidth to settle to 10 μV within 62 clock cycles.

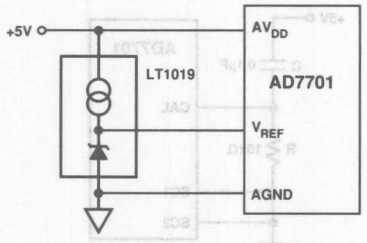

Figure 14. Typical External Reference Connections

The digital filter of the AD7701 removes noise from the reference input, just as it does with noise at the analog input, and the same limitations apply regarding lack of noise rejection at integer multiples of the sampling frequency. If reference noise is a problem, some voltage references offer noise reduction schemes using an external capacitor. Alternatively, a simple RC filter may be used, as shown in Figure 15.

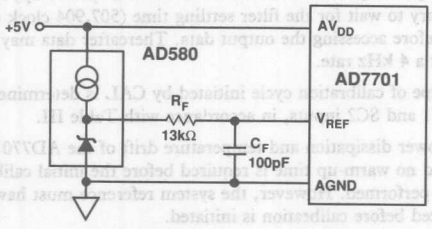

Figure 15. Filtered Reference Input

The same considerations apply to this filter as to a filter at the analog input. In this case:

$$[R_F\,(C_F + 10\,pF)] = \frac{62}{f_{CLKIN} \cdot In\left[\frac{100\,mV \cdot C_{IN}\,(C_{IN} + C_F)}{V_{FSE}}\right]}$$

where:

f_{CLKIN} is the master clock frequency

and

V_{FSE} is the maximum desired error in volts.

GROUNDING AND SUPPLY DECOUPLING

AGND is the ground reference voltage for the AD7701, and is completely independent of DGND. Any noise riding on the AGND input with respect to the system analog ground will cause conversion errors. AGND should therefore be used as the system ground and also as the ground for the analog input and the reference voltage.

The analog and digital power supplies to the AD7701 are independent and separately pinned out, to minimize coupling between analog and digital sections of the device. The digital filter will provide rejections of broadband noise on the power supplies, except at integer multiples of the sampling frequency. Therefore, the two analog supplies should be decoupled to AGND using 100 nF ceramic capacitors to provide power supply noise rejections at these frequencies. The two digital supplies should similarly be decoupled to DGND.

ACCURACY AND AUTOCALIBRATION

Sigma delta ADCs, like VFCs and other integrating ADCs, do not contain any source of nonmonotonicity and inherently offer no-missing-codes performance. The AD7701 achieves excellent linearity (±0.0007%) by the use of high quality, on-chip silicon dioxide capacitors, which have a very low capacitance/voltage coefficient.

The AD7701 offers two self-calibration modes using the on-chip calibration microcontroller and SRAM. Table III is a truth table for the calibration control inputs SC1 and SC2.

In the self-calibration mode, zero-scale is calibrated against the AGND pin and full scale is calibrated against the V_{REF} pin, to remove internal errors.

Note that in the bipolar mode the AD7701 calibrates positive full scale and midscale (bipolar zero).

In the system-calibration mode, the AD7701 calibrates its zero and full scale to voltages present on the analog input pin in two sequential steps. This allows system offsets and/or gain errors to be nulled out.

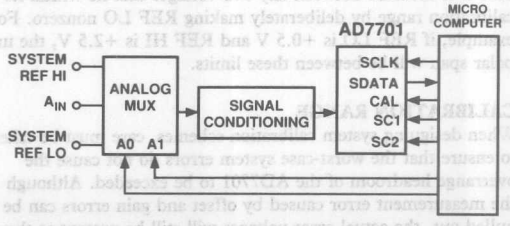

Figure 16. Typical Connections for System Calibration

A typical system calibration scheme is shown in Figure 16. In normal operation the analog signal is fed to the AD7701 via an analog multiplexer. When the system is to be calibrated, A_{IN} is first switched to the system REF LO via the multiplexer and CAL is strobed high, with SC1 and SC2 both high. A_{IN} is then switched to the system REF HI and CAL is strobed, with SC1 low and SC2 high. In this way, the effect of all error sources

CAL	SC1	SC2	CAL TYPE	ZERO REFERENCE	FS REFERENCE	SEQUENCE	CALIBRATION TIME
⎍	0	0	Self-Cal	AGND	V_{REF}	One Step	3,145,655 Clock Cycles
⎍	1	1	System Offset	A_{IN}	–	1st Step	1,052,599 Clock Cycles
⎍	0	1	System Gain	–	A_{IN}	2nd Step	1,068,813 Clock Cycles
⎍	1	0	System Offset	A_{IN}	V_{REF}	One Step	2,117,389 Clock Cycles

NOTE
$\overline{DRDY}$ remains high throughout the calibration sequence. In the Self-Cal mode, $\overline{DRDY}$ falls once the AD7701 has settled to the analog input. In all other modes $\overline{DRDY}$ falls as the device begins to settle.

Table III. Calibration Truth Table

between the multiplexer and the AD7701 is removed. Op amps and other signal conditioning circuits may be used in front of the AD7701, without worrying about their absolute gain or offset errors. Note that the absolute value of the reference supplied to the AD7701 is no longer important, provided it has adequate short-term stability between calibration cycles, as full scale is calibrated to the system reference.

If system offset errors are important but system gain errors are not, then a one step system calibration may be performed with SC1 high and SC2 low. In this case, offset is calibrated against A_{IN}, which should be connected to system REF LO during calibration, but full scale is calibrated against the AD7701's V_{REF} input.

System calibration schemes will yield better accuracy than self-calibration, even if there are no system errors. Using self-calibration, errors arise due to the mismatch in source impedances between the references during calibration (AGND and V_{REF}) and the analog input during normal operation. In system calibration, the source impedances inherently remain identical, such that the theoretical limit to system accuracy is calibration resolution. The practical limit is the noise floor of the AD7701.

Note that in system calibration, "REF LO" does not necessarily mean the system ground or zero volts. The AD7701 can be calibrated to measure between any two voltages that lie within its calibration range by deliberately making REF LO nonzero. For example, if REF LO is +0.5 V and REF HI is +2.5 V, the unipolar span will be between these limits.

CALIBRATION RANGE

When designing system calibration schemes, care must be taken to ensure that the worst-case system errors do not cause the overrange headroom of the AD7701 to be exceeded. Although the measurement error caused by offset and gain errors can be nulled out, the actual error voltages will still be present at the analog input and can cause overloading of the analog modulator or overflow of the digital filter. With a 2.5 V reference, the maximum input voltage is ($+V_{REF}$ + 100 mV), and the minimum input voltage is ($-V_{REF}$ − 100 mV).

POWER UP AND CALIBRATION

A calibration cycle must be carried out after power up to initialize the device to a consistent starting condition and correct calibration. The CAL pin must be held high for at least four clock cycles, after which calibration is initiated on the falling edge of CAL and takes a maximum of 3,145,655 clock cycles (approximately 768 ms , with a 4.096 MHz clock). See Table III.

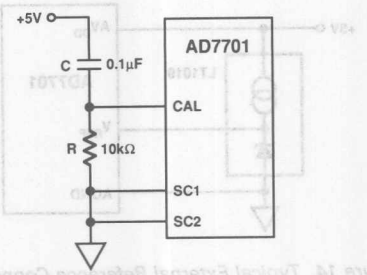

Figure 17. Power-On Reset Circuit

Figure 17 shows a simple RC circuit which will briefly pull the CAL input high as power applied. For this circuit to work the power supply must come up cleanly without oscillation, otherwise the internal circuits of the AD7701 may not all recognize the same reset transition. This can be overcome by using a Schmitt-trigger inverter between the RC combination and the CAL input to provide a clean transition. After power up, it is necessary to wait for the filter settling time (507,904 clock cycles) before accessing the output data. Thereafter data may be read at a 4 kHz rate.

The type of calibration cycle initiated by CAL is determined by the SC1 and SC2 inputs, in accordance with Table III.

The power dissipation and temperature drift of the AD7701 are low and no warm-up time is required before the initial calibration is performed. However, the system reference must have stabilized before calibration is initiated.

POWER SUPPLY SEQUENCING

The positive digital supply (DV_{DD}) must never exceed the positive analog supply (AV_{DD}) by more than 0.3 V. Power supply sequencing is therefore important. If separate analog and digital supplies are used, care must be taken to ensure that the analog supply is powered up first.

It is also important that power is applied to the AD7701 before signals at V_{REF}, A_{IN} or the logic input pins in order to avoid any possibility of latch-up. If separate supplies are used for the AD7701 and the system digital circuitry, then the AD7701 should be powered up first.

A typical scheme for powering the AD7701 from a single set of ±5 V rails is shown in the system connection diagram, Figure 7. In this circuit AV_{DD} and DV_{DD} are brought along separate tracks from the same +5 V supply. Thus, there is no possibility of the digital supply coming up before the analog supply.

GROUNDING

The AD7701 uses the analog ground connection, AGND, as the measurement reference node. It should be used as the reference node for both the analog input signal and the reference voltage at the V_{REF} pin.

The analog and digital power supplies to the AD7701 die are pinned out separately to minimize coupling between the analog and digital sections of the chip. All four supplies should be decoupled separately to their respective grounds as shown in Figure 7. The on-chip digital filtering of the AD7701 further enhances power supply rejection by attenuating noise injected into the conversion process.

SINGLE SUPPLY OPERATION

Figure 18 shows a circuit to power the AD7701 from a single +10 V supply, using an op amp to provide a half supply reference point for AGND and DGND. As the digital I/O pins ar referenced to this point, level shifting is required for external digital communications. If galvanic isolation is required in the system, level shifting and isolation can both be provided by opto-isolators.

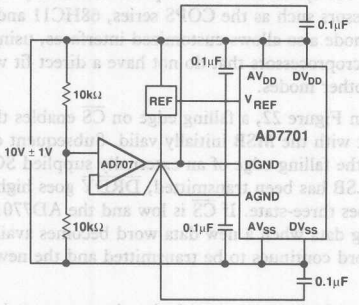

Figure 18. Single Supply Operation

SLEEP MODE

The low power standby mode is initiated by taking the $\overline{\text{SLEEP}}$ input low, which shuts down all analog and digital circuits and reduces power consumption to 10 µW. The calibration coefficients are still retained in memory, but as the converter has been quiescent, it is necessary to wait for the filter settling time (507,904 cycles) before accessing the output data.

BATTERY BACKUP OF CALIBRATION COEFFICIENTS

The calibration data stored in the AD7701's static RAM is lost whenever power is removed. In certain applications it may be desirable to protect the contents of the calibration SRAM against intermittent power loss, for example when a mains powered instrument is moved to a different location.

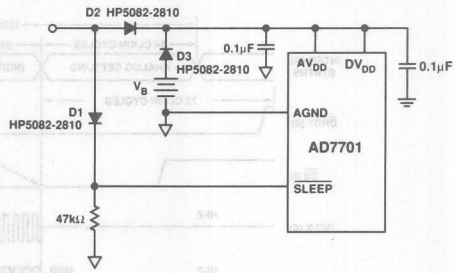

Figure 19. Battery Backup of Calibration Data

Figure 19 shows a simple battery backup circuit that maintains power to the SRAM during loss of the main +5 V supply. When power is lost, the $\overline{\text{SLEEP}}$ input goes low, reducing the power consumption to typically 10 µW, and a battery takes over from the main power supply. Note that AV_{DD} and DV_{DD} must both remain powered to retain the calibration memory. 3.6 V lithium batteries are available which can provide 1750 mA-hours before they drop below the 2 V memory-retention threshold of the AD7701. This translates to a memory-retention period of 20 years in the Sleep mode, allowing one time factory calibration of a system.

It should be noted that in this simple circuit, the supply voltage will fall below the battery voltage before it falls below the $\overline{\text{SLEEP}}$ pin threshold, and the battery will be supplying the full 4 mA operating current of the AD7701 until the supply falls below the logic 0 voltage of the $\overline{\text{SLEEP}}$ pin. This can cause excessive battery drain if power loss is frequent or the supply voltage falls slowly, for example if there are large reservoir capacitors in the system. In this case, the backup circuit should be designed so that voltage on $\overline{\text{SLEEP}}$ falls to 0.8 V before the supply voltage falls below 3.6 V.

DIGITAL INTERFACE

The AD7701's serial communications port allows easy interfacing to industry-standard microprocessors. Three different modes of operations are available, optimized for different types of interface.

SYNCHRONOUS SELF-CLOCKING MODE (SSC)

The SSC mode (MODE pin high) allows easy interfacing to serial-parallel conversion circuits in systems with parallel data communication. This mode allows interfacing to 74XX299 Universal Shift registers without any additional decoding. The SSC mode can also be used with microprocessors such as the 68HC11 and 68HC05, which allow an external device to clock their serial port.

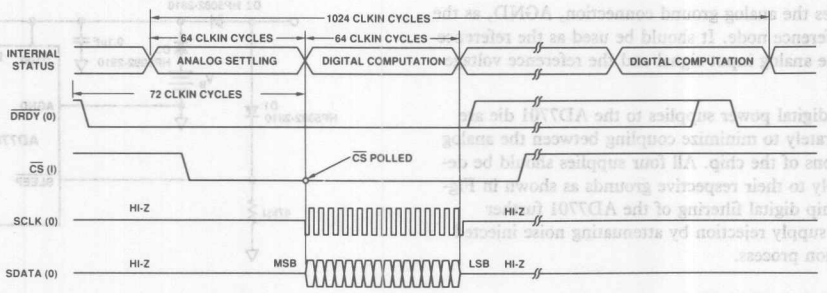

Figure 20. Timing Diagram for SSC Data Transmission Mode

Figure 20 shows the timing diagram for the SSC mode. Data is clocked out by an internally generated serial clock. The AD7701 divides each sampling interval into sixteen distinct periods. Eight periods of 64 clock pulses are for analog settling and eight periods of 64 clock pulses are for digital computation. The status of $\overline{CS}$ is polled at the beginning of each digital computation period. If it is low at any of these times then SCLK will become active and the data word currently in the output register will be transmitted, MSB first. After the LSB has been transmitted $\overline{DRDY}$ goes high and SDATA goes three-state. If $\overline{CS}$, having been brought low, is taken high again at any time during data transmission, SDATA and SCLK will go three-state after the current bit finishes. If $\overline{CS}$ is subsequently brought low, transmission will resume with the next bit during the subsequent digital computation period. If transmission has not been initiated and completed by the time the next data word is available, $\overline{DRDY}$ will go high for four clock cycles then low again as the new word is loaded into the output register.

A more detailed diagram of the data transmission in the SSC mode is shown in Figure 21. Data bits change on the falling edge of SCLK and are valid on the rising edge of SCLK.

SYNCHRONOUS EXTERNAL CLOCK MODE (SEC)

The SEC mode (MODE pin grounded) is designed for direct interface to the synchronous serial ports of industry-standard microprocessors such as the COPS series, 68HC11 and 68HC05. The SEC mode also allows customized interfaces, using I/O port pins, to microprocessors that do not have a direct fit with the AD7701's other modes.

As shown in Figure 22, a falling edge on $\overline{CS}$ enables the serial data output with the MSB initially valid. Subsequent data bits change on the falling edge of an externally supplied SCLK. After the LSB has been transmitted, $\overline{DRDY}$ goes high and SDATA goes three-state. If $\overline{CS}$ is low and the AD7701 is still transmitting data when a new data word becomes available, the old data word continues to be transmitted and the new data is lost.

If $\overline{CS}$ is taken high at any time during data transmission, SDATA will go three-state immediately. If $\overline{CS}$ returns low, the AD7701 will continue transmission with the same data bit. If transmission has not been initiated and completed by the time the next data word becomes available, and if $\overline{CS}$ is high, $\overline{DRDY}$ will return high for four clock cycles, then fall as the new word is loaded into the output register.

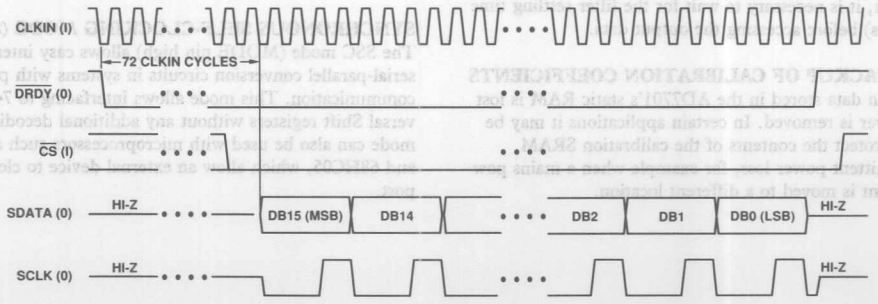

Figure 21. SSC Mode Showing Data Timing Relative to SCLK

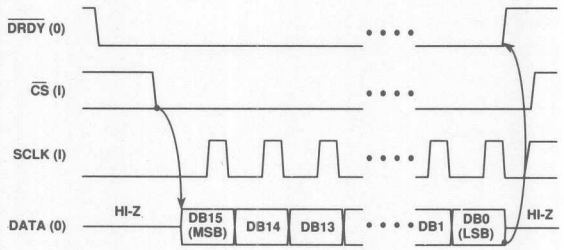

Figure 22. Timing Diagram for the SEC Mode

ASYNCHRONOUS COMMUNICATIONS (AC) MODE

The AC mode (MODE pin tied to −5 V) offers a UART-compatible interface which allows the AD7701 to transmit data asynchronously from remote locations. An external SCLK sets the baud rate and data is transmitted in two bytes in UART-compatible format. Using the AC mode, the AD7701 can be interfaced direct to microprocessors with UART interfaces, such as the 8051 and TMS70X2.

Data transmission is initiated by $\overline{CS}$ going low. If $\overline{CS}$ is low on a falling edge of SCLK, the AD7701 begins transmitting an 8-bit data byte (DB8 – DB15) with one start bit and two stop bits, as in Figure 18. The SDATA output will then go three-state. The second byte is transmitted by bringing $\overline{CS}$ low again and DB0 to DB7 are transmitted in the same format as the first byte.

UART baud rates are typically low compared to the AD7701's 4 kHz output update rate. If $\overline{CS}$ is low and data is still being transmitted when a new data word becomes available, the new data will be ignored. However, if $\overline{CS}$ has been taken high between bytes, when a new data word becomes available, the AD7701 could update the output register before the second byte is transmitted. In this case, the UART would receive the first byte of the new word instead of the second byte of the old word. When using the AC mode, care must obviously be taken to ensure that this does not occur.

DIGITAL NOISE AND OUTPUT LOADING

As mentioned earlier, the AD7701 divides its internal timing into two distinct phases, analog sampling and settling and digital computation. In the SSC mode, data is transmitted only during the digital computation periods, to minimize the effects of digital noise on analog performance. In the SEC and AC modes data transmission is externally controlled, so this automatic safeguard does not exist.

Whatever mode of operation is used, resistive and capacitive loads on digital outputs should be minimized in order to reduce crosstalk between analog and digital portions of the circuit. For this reason connection to low-power CMOS logic such as one of the 4000 series or 74C families is recommended.

It is especially important to minimize the load on SDATA in the AC mode, as transmission in this mode is inherently asynchronous. In the SEC mode the AD7701 should be synchronized to the digital system clock via CLKIN.

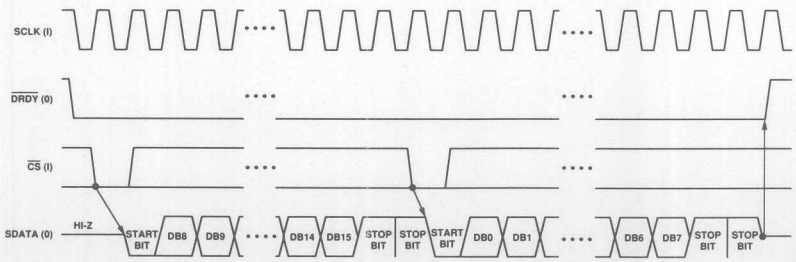

Figure 23. Timing Diagram for Asynchronous Communications Mode

LC²MOS 20-Bit A/D Converter

AD7703

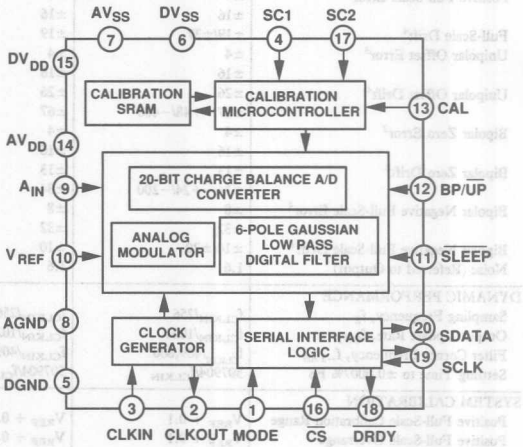
FEATURES

Monolithic 20-Bit ADC
0.0003% Linearity Error
20-Bit No Missed Codes
On-Chip Self-Calibration Circuitry
Programmable Low-Pass Filter
0.1 Hz to 10 Hz Corner Frequency
0 to +2.5 V or ±2.5 V Analog Input Range
4 kSPS Output Data Rate
Flexible Serial Interface
Ultralow Power

APPLICATIONS

Industrial Process Control
Weigh Scales
Portable Instrumentation
Remote Data Acquisition

GENERAL DESCRIPTION



The AD7703 is a 20-bit ADC which uses a sigma delta conversion technique. The analog input is continuously sampled by an analog modulator whose mean output duty cycle is proportional to the input signal. The modulator output is processed by an on-chip digital filter with a six-pole Gaussian response, which updates the output data register with 20-bit binary words at word rates up to 4 kHz. The sampling rate, filter corner frequency and output word rate are set by a master clock input that may be supplied externally, or by an on-chip gate oscillator.

The inherent linearity of the ADC is excellent, and endpoint accuracy is ensured by self-calibration of zero and full scale which may be initiated at any time. The self-calibration scheme can also be extended to null system offset and gain errors in the input channel.

The output data is accessed through a serial port, which has two synchronous modes suitable for interfacing to shift registers or the serial ports of industry standard microcontrollers.

CMOS construction ensures low power dissipation, and a power down mode reduces the idle power consumption to only 10 μW.

FUNCTIONAL BLOCK DIAGRAM

PRODUCT HIGHLIGHTS

1. The AD7703 offers 20-bit resolution coupled with outstanding 0.0003% accuracy.
2. No missing codes ensures true, usable, 20-bit dynamic range, removing the need for programmable gain and level-setting circuitry.
3. The effects of temperature drift are eliminated by on-chip self-calibration, which removes zero and gain error. External circuits can also be included in the calibration loop to remove system offsets and gain errors.
4. A flexible synchronization allows the AD7703 to interface directly to the serial ports of industry standard microcontrollers and DSP processors.
5. Low operating power consumption and an ultralow power standby mode make the AD7703 ideal for loop powered remote sensing applications, or battery-powered portable instruments.

AD7703—SPECIFICATIONS

(T_A = +25°C; AV_{DD} = DV_{DD} = +5 V; AV_{SS} = DV_{SS} = −5 V; V_{REF} = +2.5 V; f_{CLKIN} = 4.096 MHz; BP/UP = +5 V; MODE = +5 V; A_{IN} Source Resistance = 750 Ω[1] with 1 nF to AGND at A_{IN} unless otherwise stated.)

NOTES

[1]The A_{IN} pin presents a very high impedance dynamic load which varies with clock frequency. A ceramic 1 nF capacitor from the A_{IN} to AGND is necessary. Source resistance should be 750 Ω or less.

[2]Temperature Ranges are as follows: A, B, C Versions: −40°C to +85°C; S Version: −55°C to +125°C.

[3]Applies after calibration at the temperature of interest. Full-Scale Error applies for both unipolar and bipolar input ranges.

[4]Total drift over the specified temperature range after calibration at power-up at +25°C. This is guaranteed by design and/or characterization. Recalibration at any temperature will remove these errors.

[5]In unipolar mode the offset can have a negative value ($-V_{REF}$) such that the unipolar mode can mimic bipolar mode operation.

[6]The specifications for input overrange and for input span apply additional constraints on the offset calibration range.

[7]For unipolar mode, input span is the difference between full scale and zero scale. For bipolar mode, input span is the difference between positive and negative full-scale points. When using less than the maximum input span, the span range may be placed anywhere within the range of $\pm(V_{REF} + 0.1)$.

[8]All digital outputs unloaded. All digital inputs at 5 V CMOS levels.

[9]Applies in 0.1 Hz to 10 Hz bandwidth. PSRR at 60 Hz will exceed 120 dB due to the digital filter.

[10]CLKIN is stopped. All digital inputs are grounded.

Specifications subject to change without notice.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

[1]Transient currents of up to 100 mA will not cause SCR latch-up.

NOTES

[1]N = Plastic DIP; R = SOIC; Q = Cerdip. For outline information see Package Information section.

[2]Available to /883B processing only. Contact local sales office for military data sheet.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

TIMING CHARACTERISTICS[1, 2] (AV_{DD} = DV_{DD} = +5 V ± 10%; AV_{SS} = DV_{SS} = −5 V ± 10%; AGND = DGND = 0 V; f_{CLKIN} = 4.096 MHz; Input Levels: Logic 0 = 0 V, Logic 1 = DV_{DD}; unless otherwise stated.)

t_{15}[8]	250	250	ns min	$\overline{CS}$ High to Hi-Z Delay
t_{16}[8]	200	200	ns min	SCLK Falling Edge to Hi-Z Delay. Typically 100 ns

NOTES

[1]Sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

[2]See Figures 1 to 6.

[3]CLKIN duty cycle range is 20% to 80%. CLKIN must be supplied whenever the AD7703 is not in SLEEP mode. If no clock is present in this case, the device can draw higher current than specified and possibly become uncalibrated.

[4]The AD7703 is production tested with f_{CLKIN} at 4.096 MHz. It is guaranteed by characterization to operate at 200 kHz.

[5]Specified using 10% and 90% points on waveform of interest.

[6]In order to synchronize several AD7703s together using the $\overline{SLEEP}$ pin, this specification must be met.

[7]t_4 and t_{13} are measured with the load circuit of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.

[8]t_9, t_{10}, t_{15} and t_{16} are derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove the effects of charging or discharging the 100 pF capacitor. This means that the time quoted in the Timing Characteristics is the true bus relinquish time of the part and as such is independent of external bus loading capacitances.

[9]If $\overline{CS}$ is returned high before all 20 bits are output, the SDATA and SCLK outputs will complete the current data bit and then go to high impedance.

[10]If $\overline{CS}$ is activated asynchronously to $\overline{DRDY}$, $\overline{CS}$ will not be recognized if it occurs when $\overline{DRDY}$ is high for four clock cycles. The propagation delay time may be as great as 4 CLKIN cycles plus 160 ns. To guarantee proper clocking of SDATA when using asynchronous $\overline{CS}$, The SCLK input should not be taken high sooner than 4 CLKIN cycles plus 160 ns after $\overline{CS}$ goes low.

[11]SDATA is clocked out on the falling edge of the SCLK input.

TERMINOLOGY

LINEARITY ERROR

This is the maximum deviation of any code from a straight line passing through the endpoints of the transfer function. The endpoints of the transfer function are zero-scale (not to be confused with bipolar zero), a point 0.5 LSB below the first code transition (000 . . . 000 to 000 . . . 001) and full scale, a point 1.5 LSB above the last code transition (111 . . . 110 to 111 . . . 111). The error is expressed as a percentage of full scale.

DIFFERENTIAL LINEARITY ERROR

This is the difference between any code's actual width and the ideal (1 LSB) width. Differential linearity error is expressed in LSBs. A differential linearity specification of ±1 LSB or less guarantees monotonicity.

POSITIVE FULL-SCALE ERROR

Positive full-scale error is the deviation of the last code transition (111 . . . 110 to 111 . . . 111) from the ideal (V_{REF} − 3/2 LSBs). It applies to both positive and negative analog input ranges.

UNIPOLAR OFFSET ERROR

Unipolar offset error is the deviation of the first code transition from the ideal (AGND + 0.5 LSB) when operating in the unipolar mode.

BIPOLAR ZERO ERROR

This is the deviation of the midscale transition (0111 . . . 111 to 1000 . . . 000) from the ideal (AGND − 0.5 LSB) when operating in the bipolar mode.

BIPOLAR NEGATIVE FULL-SCALE ERROR

This is the deviation of the first code transition from the ideal ($-V_{REF}$ + 0.5 LSB), when operating in the bipolar mode.

POSITIVE FULL-SCALE OVERRANGE

Positive full-scale overrange is the amount of overhead available to handle input voltages greater than $+V_{REF}$ (for example, noise peaks or excess voltages due to system gain errors in system calibration routines) without introducing errors due to overloading the analog modulator or overflowing the digital filter.

NEGATIVE FULL-SCALE OVERRANGE

This is the amount of overhead available to handle voltages below $-V_{REF}$ without overloading the analog modulator or overflowing the digital filter. Note that the analog input will accept negative voltage peaks even in the unipolar mode.

OFFSET CALIBRATION RANGE

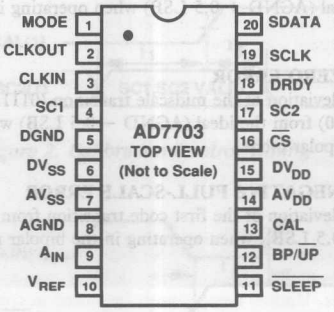
In the system calibration modes (SC2 Low) the AD7703 calibrates its offset with respect to the A_{IN} pin. The offset calibration range specification defines the range of voltages that the AD7701 can accept and still calibrate offset accurately.

FULL-SCALE CALIBRATION RANGE

This is the range of voltages that the AD7703 can accept in the system calibration mode and still calibrate full scale correctly.

INPUT SPAN

In system calibration schemes, two voltages applied in sequence to the AD7703's analog input define the analog input range. The input span specification defines the minimum and maximum input voltages from zero to full scale that the AD7703 can accept and still calibrate gain accurately.



AD7703 PIN FUNCTION DESCRIPTION

Pin	Mnemonic	Description
1	MODE	Selects the Serial Interface Mode. If MODE is tied to DGND, the Synchronous External Clocking (SEC) mode is selected. SCLK is configured as an input, and the output appears without formatting, the MSB coming first. If MODE is tied to +5 V, the AD7703 operates in the Synchronous Self-Clocking (SSC) mode. SCLK is configured as an output, with a clock frequency of $f_{CLKIN}/4$ and 25% duty cycle.
2	CLKOUT	Clock Output to generate an Internal Master Clock by connecting a crystal between CLKOUT and CLKIN. If an external clock is used, CLKOUT is left open circuit.
3	CLKIN	Clock Input for External Clock.
4, 17	SC1, SC2	System Calibration Pins. The state of these pins, when CAL is taken high, determines the type of calibration performed.
5	DGND	Digital Ground. Ground reference for all digital signals.
6	DV_{SS}	Digital Negative Supply, −5 V nominal.
7	AV_{SS}	Analog Negative Supply, −5 V nominal.
8	AGND	Analog Ground. Ground reference for all analog signals.
9	A_{IN}	Analog Input.
10	V_{REF}	Voltage Reference Input, +2.5 V nominal. This determines the value of positive full scale in the unipolar mode and of both positive and negative full-scale in the Bipolar Mode.
11	$\overline{SLEEP}$	Sleep mode pin. When this pin is taken Low, the AD7703 goes into a low-power mode with typically 10 μW power consumption.
12	BP/$\overline{UP}$	Bipolar/Unipolar mode pin. When this pin is low the AD7703 is configured for a unipolar input range of AGND to V_{REF}. When Pin 12 is High, the AD7703 is configured for a bipolar input range, $\pm V_{REF}$.
13	CAL	Calibration mode pin. When CAL is taken High for more than 4 master clock cycles, the AD7703 is reset and performs a calibration cycle when CAL is brought Low again. The CAL pin can also be used as a strobe to synchronize the operation of several AD7703s.
14	AV_{DD}	Analog Positive Supply, +5 V nominal.
15	DV_{DD}	Digital Positive Supply, +5 V nominal.
16	$\overline{CS}$	Chip Select Input. When $\overline{CS}$ is brought low, the AD7703 will begin to transmit serial data in a format determined by the state of the MODE pin.
18	$\overline{DRDY}$	Data Ready Output. $\overline{DRDY}$ is low when valid data is available in the output register. It goes High after transmission of a word is completed. It also goes High for four clock cycles when a new data word is being loaded into the output register, to indicate that valid data is not available, irrespective of whether data transmission is complete or not.
19	SCLK	Serial Clock Input/Output. The SCLK pin in configured as an input or output, dependent on the type of serial data transmission that has been selected by the MODE pin. When configured as an output in the Synchronous Self-Clocking mode, it has a frequency of $f_{CLKIN}/4$ and a duty cycle of 25%.
20	SDATA	Serial Data Output. The AD7703's output data is available at this pin as a 20-bit serial word.

PIN CONFIGURATION

GENERAL DESCRIPTION

The AD7703 is a 20-bit A/D converter with on-chip digital filtering, intended for the measurement of wide dynamic range, low frequency signals such as those representing chemical, physical or biological processes. It contains a charge-balancing (sigma delta) ADC, calibration microcontroller with on-chip static RAM, a clock oscillator and a serial communications port.

The analog input signal to the AD7703 is continuously sampled at a rate determined by the frequency of the master clock, CLKIN. A charge-balancing A/D converter (sigma delta modulator) converts the sampled signal into a digital pulse train whose duty cycle contains the digital information. A six-pole Gaussian digital low pass filter processes the output of the sigma-delta modulator and updates the 20-bit output register at a 4 kHz rate. The output data can be read from the serial port randomly or periodically at any rate up to 4 kHz.

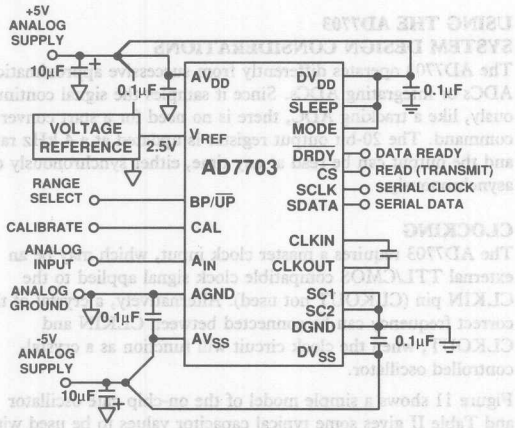

Figure 7. Typical System Connection Diagram

The AD7703 can perform self-calibration using the on-chip calibration microcontroller and SRAM to store calibration parameters. A calibration cycle may be initiated at any time using the CAL control input.

Other system components may also be included in the calibration loop to remove offset and gain errors in the input channel.

For battery operation, the AD7703 also offers a standby mode that reduces idle power consumption to typically 10 µW.

THEORY OF OPERATION

The general block diagram of a sigma-delta ADC is shown in Figure 8. It contains the following elements:

1. A sample-hold amplifier
2. A differential amplifier or subtractor
3. An analog low pass filter
4. A 1-bit A/D converter (comparator)
5. A 1-bit DAC
6. A digital low pass filter

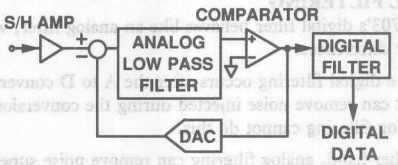

Figure 8. General Sigma Delta ADC

In operation, the sampled analog signal is fed to the subtractor, along with the output of the 1-bit DAC. The filtered difference signal is fed to the comparator, whose output samples the difference signal at a frequency many times that of the analog signal frequency (oversampling).

Oversampling is fundamental to the operation of sigma-delta ADCs. Using the quantization noise formula for an ADC:

$$SNR = (6.02 \times number\ of\ bits + 1.76)\ dB,$$

a 1-bit ADC or comparator yields an SNR of 7.78 dB.

The AD7703 samples the input signal at 16 kHz, which spreads the quantization noise from 0 to 8 kHz. Since the specified analog input bandwidth of the AD7701 is only 0 to 10 Hz, the noise energy in this bandwidth would be only 1/800 of the total quantization noise, assuming that the noise energy was spread evenly throughout the spectrum. It is reduced still further by analog filtering in the modulator loop, which shapes the quantization noise spectrum to move most of the noise energy to frequencies above 10 Hz. The SNR performance in the 0 to 10 Hz range is conditioned to the 20-bit level in this fashion.

The output of the comparator provides the digital input for the 1-bit DAC, so the system functions as a negative feedback loop which minimizes the difference signal. The digital data that represents the analog input voltage is in the duty cycle of the pulse train appearing at the output of the comparator. It can be retrieved as a parallel binary data word using a digital filter.

Sigma delta ADCs are generally described by the order of the analog low pass filter. A simple example of a first order sigma delta ADC is shown in Figure 8. This contains only a first-order low pass filter or integrator.

The AD7703 uses a second order sigma delta modulator and a digital filter that provides a rolling average of the sampled output. After power up or if there is a step change in the input voltage, there is a settling time before valid data is obtained.

The AD7703's digital filter behaves like an analog filter, with a few minor differences.

First, since digital filtering occurs after the A to D conversion process, it can remove noise injected during the conversion process. Analog filtering cannot do this.

On the other hand, analog filtering can remove noise superimposed on the analog signal before it reaches the ADC. Digital filtering cannot do this and noise peaks riding on signals near full scale have the potential to saturate the analog modulator and digital filter, even though the average value of the signal is within limits. To alleviate this problem, the AD7703 has overrange headroom built into the sigma-delta modulator and digital filter which allows overrange excursions of 100 mV. If noise signals are larger than this, consideration should be given to analog input filtering, or to reducing the gain in the input channel so that a full-scale input (2.5 V) gives only a half-scale input to the AD7703 (1.25 V). This will provide an overrange capability greater than 100% at the expense of reducing the dynamic range by 1 bit (50%).

FILTER CHARACTERISTICS

The cutoff frequency of the digital filter is $f_{CLK}/409600$. At the maximum clock frequency of 4.096 MHz, the cutoff frequency of the filter is 10 Hz and the data update rate is 4 kHz.

Figure 9 shows the filter frequency response. This is a 6-pole Gaussian response that provides 55 dB of 60 Hz rejection for a 10 Hz cutoff frequency. If the clock frequency is halved to give a 5 Hz cutoff, 60 Hz rejection is better than 90 dB.

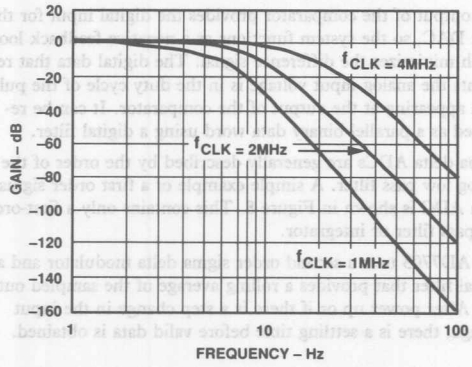

Figure 9. Frequency Response of AD7703 Filter

Since the AD7703 contains this low-pass filtering, there is a settling time associated with step function inputs, and data will be invalid after a step change until the settling time has elapsed. The AD7703 is, therefore, unsuitable for high speed multiplexing, where channels are switched and converted sequentially at high rates, as switching between channels can cause a step change in the input. However, slow multiplexing of the AD7703 is possible, provided that the settling time is allowed to elapse before data for the new channel is accessed.

The output settling of the AD7703 in response to a step input change is shown in Figure 10. The Gaussian response has fast settling with no overshoot, and the worst-case settling time to ±0.0007% is 125 ms with a 4.096 MHz master clock frequency.

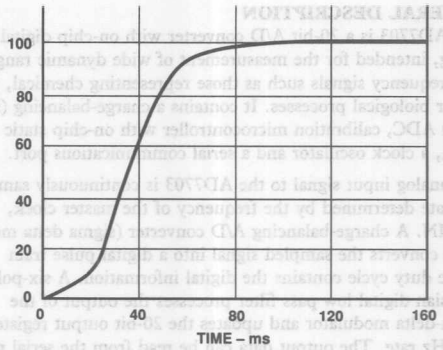

Figure 10. AD7703 Step Response

USING THE AD7703 SYSTEM DESIGN CONSIDERATIONS

The AD7703 operates differently from successive approximation ADCs or integrating ADCs. Since it samples the signal continuously, like a tracking ADC, there is no need for a start convert command. The 20-bit output register is updated at a 4 kHz rate, and the output can be read at any time, either synchronously or asynchronously.

CLOCKING

The AD7703 requires a master clock input, which may be an external TTL/CMOS compatible clock signal applied to the CLKIN pin (CLKOUT not used). Alternatively, a crystal of the correct frequency can be connected between CLKIN and CLKOUT, when the clock circuit will function as a crystal-controlled oscillator.

Figure 11 shows a simple model of the on-chip gate oscillator and Table II gives some typical capacitor values to be used with various resonators.

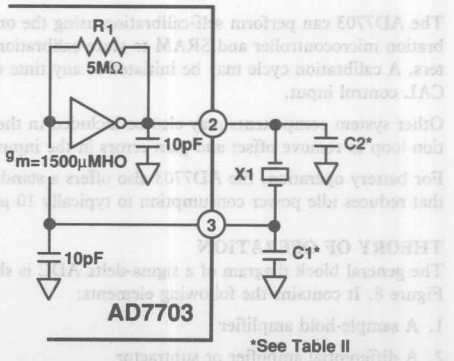

Figure 11. On-Chip Gate Oscillator

Resonators	C1	C2
Ceramic		
200 kHz	330 pF	470 pF
455 kHz	100 pF	100 pF
1.0 MHz	50 pF	50 pF
2.0 MHz	20 pF	20 pF
Crystals		
2.000 MHz	30 pF	30 pF
3.579 MHz	20 pF	20 pF
4.096 MHz	None	None

Table II. Resonator Loading Capacitors

The input sampling frequency, output data rate, filter characteristics and calibration time are all directly related to the master clock frequency f_{CLKIN} by the ratios given in the specification table under Dynamic Performance. Therefore, the first step in system design with the AD7703 is to select a master clock frequency suitable for the bandwidth and output data rate required by the application.

ANALOG INPUT RANGES

The AD7703 performs conversion relative to an externally supplied reference voltage, which allows easy interfacing to ratiometric systems. In addition, either unipolar or bipolar input voltage ranges may be selected using the BP/$\overline{UP}$ input. With BP/$\overline{UP}$ tied low, the input range is unipolar and the span is ($V_{REF} - V_{AGND}$), where V_{AGND} is the voltage at the device AGND pin. With BP/$\overline{UP}$ tied high, the input range is bipolar and the span is 2 V_{REF}. In the bipolar mode both positive and negative full scale are directly determined by V_{REF}. This offers superior tracking of positive and negative full scale and better midscale (bipolar zero) stability than bipolar schemes that simply scale and offset the input range.

The digital output coding for the unipolar range is unipolar binary and for the bipolar range it is offset binary. Bit weights for the unipolar and bipolar modes are shown in Table I.

ACCURACY

Sigma delta ADCs, like VFCs and other integrating ADCs, do not contain any source of nonmonotonicity and inherently offer no missing codes performance.

The AD7703 achieves excellent linearity by the use of high quality, on-chip silicon dioxide capacitors, which have a very low capacitance/voltage coefficient. The device also achieves low input drift through the use of chopper-stabilized techniques in its input stage. To ensure excellent performance over time and temperature, the AD7703 uses digital calibration techniques which minimize offset and gain error to typically ±4 LSBs.

AUTOCALIBRATION

The AD7703 offers both self calibration and system calibration facilities. For calibration to occur, the on-chip microcontroller must record the modulator output for two different input conditions. These are the "zero scale" and "full scale" points. In unipolar self-calibration mode, the zero scale point is V_{AGND} and the full-scale point is V_{REF}. With these readings the microcontroller can calculate the gain slope for the input to output transfer function of the converter. In unipolar mode the slope factor is determined by dividing the span between zero and full scale by 2^{20}. In bipolar mode it is determined by dividing the span by 2^{19} since the inputs applied represent only half the total codes. In both unipolar and bipolar modes the slope factor is saved and used to calculate the binary output code when an analog input is applied to the device. Table IV gives the output code size after calibration.

System calibration allows the AD7703 to compensate for system gain and offset errors. A typical circuit where this might be used is shown in Figure 12.

System calibration performs the same slope factor calculations as self calibration but uses voltage values presented by the system to the A_{IN} pin for the zero and full-scale points. There are two system calibration modes.

The first mode offers system level calibration for system offset and system gain. This is a two step operation. The zero scale point must be presented to the converter first. It must be applied to the converter before the calibration step is initiated and remain stable until the step is complete. The $\overline{DRDY}$ output from the device will signal when the step is complete by going low. After the zero scale point is calibrated the full-scale point is applied and the second calibration step is initiated. Again the voltage must remain stable throughout the calibration step.

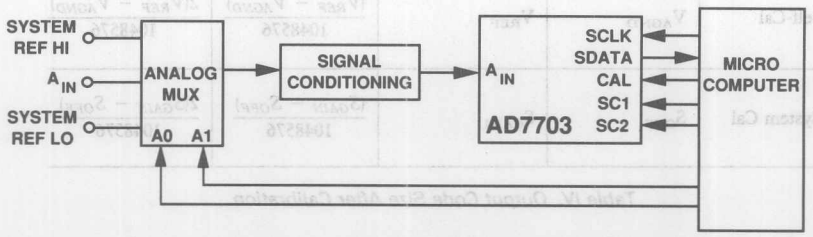

Figure 12. Typical Connections for System Calibration

The two step calibration mode offers another feature. After the sequence has been completed, additional offset calibrations can be performed by themselves to adjust the zero reference point to a new system zero reference value. This second system calibration mode uses an input voltage for the zero-scale calibration point but uses the V_{REF} value for the full-scale point.

Initiating Calibration

Table III illustrates the calibration modes available in the AD7703. Not shown in the table is the function of the BP/$\overline{UP}$ pin which determines whether the converter has been calibrated to measure bipolar or unipolar signals. A calibration step is initiated by bringing the CAL pin high for at least 4 CLKIN cycles and then bringing it low again. The states of SC1 and SC2 along with the BP/$\overline{UP}$ pin will determine the type of calibration to be performed. All three signals should be stable before the CAL pin is taken positive. The SC1 and SC2 inputs are latched when CAL goes high. The BP/$\overline{UP}$ input is not latched and therefore must remain in a fixed state throughout the calibration and measurement cycles. Any time the state of the BP/$\overline{UP}$ is changed, a new calibration cycle must be performed to enable the AD7703 to function properly in the new mode.

When a calibration step is initiated, the $\overline{DRDY}$ signal will go high and remain high until the step is finished. Table III shows the number of clock cycles each calibration requires. Once a calibration step is initiated it must finish before a new calibration step can be executed. In the two step system calibration mode, the offset calibration step must be initiated before initiating the gain calibration step.

When self-calibration is completed $\overline{DRDY}$ falls and the output port is updated with a data word that represents the analog input signal. When a system calibration step is completed, $\overline{DRDY}$ will fall and the output port will be updated with the appropriate data value (all 0s for the zero scale point and all 1s for the full-scale point). In the system calibration mode, the digital filter must settle before the output code will represent the value of the analog input signal. Tables IV and V indicate the output code size and output coding of the AD7703 in its various modes. In these tables, S_{OFF} is the measured system offset in volts and S_{GAIN} is the measured system gain at the full-scale point in volts.

Span and Offset Limits

Whenever a system calibration mode is used, there are limits on the amount of offset and span which can be accommodated. The range of input span in both the unipolar and bipolar modes has a minimum value of 0.8 V_{REF} and a maximum value of 2 (V_{REF} + 0.1 V).

The amount of offset which can be accommodated depends on whether the unipolar or bipolar mode is being used. In unipolar mode, the system calibration modes can handle a maximum offset of 0.2 V_{REF} and a minimum offset of − (V_{REF}+ 0.1 V). Thus the AD7703 in the unipolar mode can be calibrated to mimic bipolar operation.

CAL	SC1	SC2	CAL TYPE	ZERO SCALE CAL	FULL-SCALE CAL	SEQUENCE	CALIBRATION TIME
	0	0	Self-Cal	V_{AGND}	V_{REF}	One Step	3,145,655 Clock Cycles
	1	1	System Offset	A_{IN}	–	1st Step	1,052,599 Clock Cycles
	0	1	System Gain	–	A_{IN}	2nd Step	1,068,813 Clock Cycles
	1	0	System Offset	A_{IN}	V_{REF}	One Step	2,117,389 Clock Cycles

NOTE

$\overline{DRDY}$ remains high throughout the calibration sequence. In the Self-Cal mode, $\overline{DRDY}$ falls once the AD7703 has settled to the analog input. In all other modes $\overline{DRDY}$ falls as the device begins to settle.

Table III. Calibration Truth Table

			1 LSB	
CAL MODE	ZERO SCALE	GAIN FACTOR	UNIPOLAR	BIPOLAR
Self-Cal	V_{AGND}	V_{REF}	$\frac{(V_{REF} - V_{AGND})}{1048576}$	$\frac{2(V_{REF} - V_{AGND})}{1048576}$
System Cal	S_{OFF}	S_{GAIN}	$\frac{(S_{GAIN} - S_{OFF})}{1048576}$	$\frac{2(S_{GAIN} - S_{OFF})}{1048576}$

Table IV. Output Code Size After Calibration

INPUT VOLTAGE, UNIPOLAR MODE			INPUT VOLTAGE, BIPOLAR MODE	
System Cal	Self-Cal	Output Codes	Self-Cal	System-Cal
> (S_{GAIN} − 1.5 LSB)	> (V_{REF} − 1.5 LSB)	FFFFF	> (V_{REF} − 1.5 LSB)	> (S_{GAIN} − 1.5 LSB)
S_{GAIN} − 1.5 LSB	V_{REF} − 1.5 LSB	FFFFF / FFFFE	V_{REF} − 1.5 LSB	S_{GAIN} − 1.5 LSB

S_{OFF} + 0.5 LSB	V_{AGND} + 0.5 LSB	00001 / 00000	−V_{REF} + 0.5 LSB	−S_{GAIN} + 2 S_{OFF} + 0.5 LSB
<(S_{OFF} + 0.5 LSB)	<(V_{AGND} + 0.5 LSB)	00000	<(−V_{REF} + 0.5 LSB)	<(−S_{GAIN} +2 S_{OFF} + 0.5 LSB)

Table V. AD7703 Output Coding

In the bipolar mode the system offset calibration range is restricted to ±0.4 V_{REF}. It should be noted that the span restrictions limit the amount of offset which can be calibrated. The span range of the converter in bipolar mode is equidistant around the voltage used for the zero scale point. When the zero-scale point is calibrated it must not cause either of the two endpoints of the bipolar transfer function to exceed the positive or the negative input overrange points (+V_{REF} + 0.1) V or −(V_{REF} + 0.1) V. If the span range is set to a minimum (0.8 V_{REF}) the offset voltage can move ±0.4 V_{REF} without causing the end points of the transfer function to exceed the overrange points. Alternatively, if the span range is set to 2 V_{REF}, the input offset cannot move more than +0.1 V or −0.1 V before an endpoint of the transfer function exceeds the input overrange limit.

POWER UP AND CALIBRATION

A calibration cycle must be carried out after power up to initialize the device to a consistent starting condition and correct calibration. The CAL pin must be held high for at least four clock cycles, after which calibration is initiated on the falling edge of CAL and takes a maximum of 3,145,655 clock cycles (approximately 768 ms with a 4.096 MHz clock). See Table III.

Figure 13 shows a simple RC circuit which will briefly pull the CAL input High as power is applied. For this circuit to work the power supply must come up cleanly without oscillation, otherwise the internal circuits of the AD7703 may not all recognize the same reset transition. This can be overcome by using a Schmitt-trigger inverter between the RC combination and the CAL input, to provide a single transition. After power up, it is necessary to wait for the filter settling time (507,904 clock cycles) before accessing the output data. Thereafter data may be read at a 4 kHz rate.

The type of calibration cycle initiated by CAL is determined by the SC1 and SC2 inputs, in accordance with Table III.

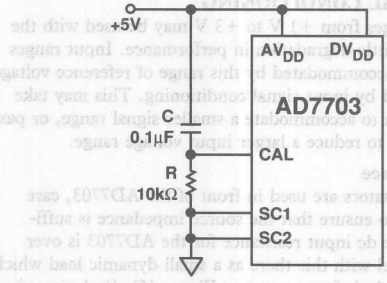

Figure 13. Power-On Reset Circuit

Drift Considerations

The AD7703 uses chopper stabilization techniques to minimize input offset drift. Charge injection in the analog switches and leakage currents at the sampling node are the primary sources of offset voltage drift in the converter. Figure 14 indicates the typical offset due to temperature changes after calibration at 25°C. Drift is relatively flat up to 75°C. Above this temperature, leakage current becomes the main source of offset drift. Since leakage current doubles approximately every 10°C, the offset drifts accordingly. The value of the voltage on the sample capacitor is updated at a rate determined by the master clock, therefore the amount of offset drift which occurs will be proportional to the elapsed time between samples. Thus, to minimize offset drift at higher temperatures, higher CLKIN rates are recommended.

Gain drift within the converter depends mainly upon the temperature tracking of the internal capacitors. It is not affected by leakage currents so that it is significantly less than offset drift. The typical gain drift of the AD7703 is less than 40 LSBs over the specified temperature range.

Measurement errors due to offset drift or gain drift can be eliminated at any time by recalibrating the converter. Using the system calibration mode can also minimize offset and gain errors in the signal conditioning circuitry. Integral and differential linearity are not significantly affected by temperature changes.

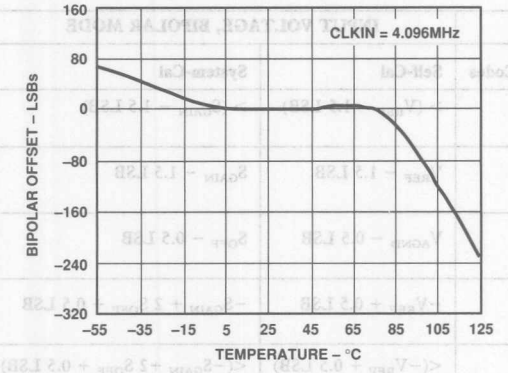

Figure 14. Typical Bipolar Offset vs. Temperature after Calibration at 25°C

INPUT SIGNAL CONDITIONING

Reference voltages from +1 V to +3 V may be used with the AD7703, with little degradation in performance. Input ranges that cannot be accommodated by this range of reference voltages may be achieved by input signal conditioning. This may take the form of gain to accommodate a smaller signal range, or passive attenuation to reduce a larger input voltage range.

Source Resistance

If passive attenuators are used in front of the AD7703, care must be taken to ensure that the source impedance is sufficiently low. The dc input resistance for the AD7703 is over 1 GΩ. In parallel with this there as a small dynamic load which varies with the clock frequency (see Figure 15). Each time the

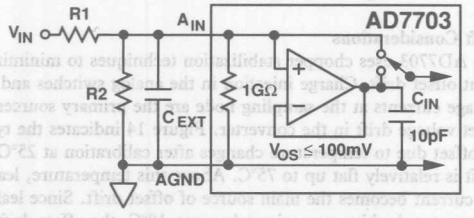

Figure 15. Equivalent Input Circuit and Input Attenuator

analog input is sampled, a 10 pF capacitor draws a charge packet of maximum 1 pC (10 pF × 100 mV) from the analog source with a frequency $f_{CLKIN}/256$. For a 4.096 MHz CLKIN, this yields an average current draw of 16 nA. After each sample the AD7703 allows 62 clock periods for the input voltage to settle. The equation which defines settling time is:

$$V_O = V_{IN}[1 - e^{-t/RC}]$$

where V_O is the final settled value, V_{IN} is the value of the input signal, R is the value of the input source resistance, C is the 10 pF sample capacitor. The value of t is equal to $62/f_{CLKIN}$. The following equation can be developed which gives the maximum allowable source resistance, $R_{S(MAX)}$, for an error of V_E.

$$R_{S(MAX)} = \frac{62}{f_{CLKIN} \cdot (10\ pF) \cdot 1\ n\ (100mV/V_E)}$$

Provided the source resistance is less than this value, the analog input will settle within the desired error band in the requisite 62 clock periods. Insufficient settling leads to offset errors. These can be calibrated in system calibration schemes.

If a limit of 600 nV (0.25 LSB at 20 bits) is set for the maximum offset voltage, then the maximum allowable source resistance is 125 kΩ from the above equation, assuming that there is no external stray capacitance.

An RC filter may be added in front of the AD7703 to reduce high frequency noise. With an external capacitor added from A_{IN} to AGND, the following equation will specify the maximum allowable source resistance:

$$R_{S(MAX)} = \frac{62}{f_{CLKIN} \cdot (C_{IN} + C_{EXT}) \cdot 1\ n \left[\frac{100\ mV \cdot \frac{C_{IN}}{(C_{IN} + C_{EXT})}}{V_E}\right]}$$

The practical limit to the maximum value of source resistance is thermal (Johnson) noise. A practical resistor may by modeled as an ideal (noiseless) resistor in series with a noise voltage source or in parallel with a noise current source.

$$V_n = \sqrt{4\ kTRf}\ Volts$$

$$i_n = \sqrt{4\ kTf/R}\ Amperes$$

where k is Boltzmann's constant (1.38×10^{-23} J/K), and T is temperature in degrees Kelvin (°C + 273).

Active signal conditioning circuits such as op amps generally do not suffer from problems of high source impedance. Their open-loop output resistance is normally only tens of ohms and, in any case, most modern general purpose op amps have sufficiently fast closed loop settling time for this not to be a problem. Offset voltage in op amps can be eliminated in a system calibration routine.

Antialias Considerations

The digital filter of the AD7703 does not provide any rejection at integer multiples of the sampling frequency ($nf_{CLKIN}/256$, where n = 1, 2, 3, . .).

With a 4.096 MHz master clock there are narrow (±10 Hz) bands at 16 kHz, 32 kHz, 48 kHz, etc., where noise passes unattenuated to the output.

However, due to the AD7703's high oversampling ratio of 800 (16 kHz to 20 Hz) these bands occupy only a small fraction of the spectrum, and most broadband noise is filtered.

The reduction in broadband noise is given by:

$$e_{out} = e_{in}\sqrt{2f_C / f_S} = 0.035\ e_{in}$$

where e_{in} and e_{out} are rms noise terms referred to the input and f_C is the filter −3 dB corner frequency ($f_{CLKIN}/409600$) and f_S is the sampling frequency ($f_{CLKIN}/256$).

Since the ratio of f_S to f_{CLKIN} is fixed, the digital filter reduces broadband white noise by 96.5% independent of the master clock frequency.

VOLTAGE REFERENCE CONNECTIONS

The voltage applied to the V_{REF} pin defines the analog input range. The specified reference voltage is 2.5 V, but the AD7703 will operate with reference voltages from 1 V to 3 V with little degradation in performance.

The reference input presents exactly the same dynamic load as the analog input, but in the case of the reference input, source resistance and long settling time introduce gain errors rather than offset errors. Fortunately, most precision references have sufficiently low output impedance and wide enough bandwidth to settle to the required accuracy within 62 clock cycles.

The digital filter of the AD7703 removes noise from the reference input, just as it does with noise at the analog input, and the same limitations apply regarding lack of noise rejection at integer multiples of the sampling frequency. Note that the reference should be chosen to minimize noise below 10 Hz. The AD7703 typically exhibits 1.6 LSB rms noise in its measurements. This specification assumes a clean reference. Many monolithic bandgap references are available which can supply the 2.5 V needed for the AD7703. However, some of these are not specified for noise especially in the 0.1 Hz to 10 Hz bandwidth. If the reference noise in this bandwidth is excessive, it can degrade the performance of the AD7703. Recommended references are the AD580 and the LT1019. Both of these 2.5 V references typically have less than 10 μV p–p noise in the 0.1 Hz to 10 Hz band.

POWER SUPPLIES AND GROUNDING

AGND is the ground reference voltage for the AD7703, and is completely independent of DGND. Any noise riding on the AGND input with respect to the system analog ground will cause conversion errors. AGND should therefore be used as the system ground and also as the ground for the analog input and the reference voltage.

The analog and digital power supplies to the AD7703 are independent and separately pinned out, to minimize coupling between analog and digital sections of the device. The digital filter will provide rejection of broadband noise on the power supplies, except at integer multiples of the sampling frequency. Therefore, the two analog supplies should be individually decoupled to AGND using 100 nF ceramic capacitors to provide power supply noise rejection at these frequencies. The two digital supplies should similarly be decoupled to DGND.

The positive digital supply (DV_{DD}) must never exceed the positive analog supply (AV_{DD}) by more than 0.3 V. Power supply sequencing is therefore important. If separate analog and digital supplies are used, care must be taken to ensure that the analog supply is powered up first.

It is also important that power is applied to the AD7703 before signals at V_{REF}, A_{IN} or the logic input pins in order to avoid any possibility of latch-up. If separate supplies are used for the AD7703 and the system digital circuitry, then the AD7703 should be powered up first.

A typical scheme for powering the AD7703 from a single set of ±5 V rails is shown Figure 7. In this circuit AV_{DD} and DV_{DD} are brought along separate tracks from the same +5 V supply. Thus, there is no possibility of the digital supply coming up before the analog supply.

SLEEP MODE

The low power standby mode is initiated by taking the $\overline{SLEEP}$ input low, which shuts down all analog and digital circuits and reduces power consumption to 10 μW. When coming out of SLEEP mode it is sometimes possible (when using a crystal to generate CLKIN, for example) to lose the calibration coefficients. Therefore, it is advisable as a safeguard to always do a calibration cycle after coming out of SLEEP mode.

BATTERY BACKUP OF CALIBRATION COEFFICIENTS

The calibration data stored in the AD7703's static RAM is lost whenever power is removed. In certain applications it may be desirable to protect the contents of the calibration SRAM against intermittent power loss, for example when a mains powered instrument is moved to a different location.

Figure 16 shows a simple battery backup circuit that maintains power to the SRAM during loss of the main +5 V supply. When power is lost, the $\overline{SLEEP}$ input goes low, reducing the power consumption to typically 10 μW, and a battery takes over from the main power supply. Note that AV_{DD} and DV_{DD} must both remain powered to retain the calibration memory. 3.6 V lithium batteries are available which can provide 1750 mA hours before they drop below the 2 V memory retention threshold of the AD7703. This translates to a memory-retention period of 20 years in the Sleep mode, allowing one time factory calibration of a system.

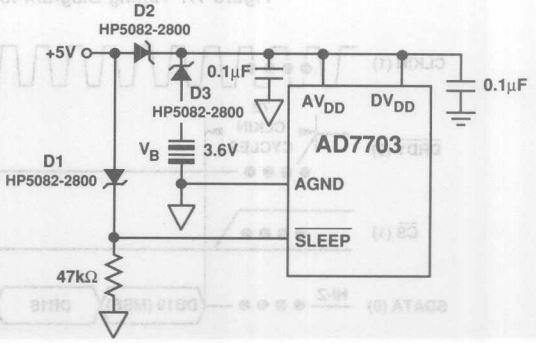

Figure 16. Battery Backup of Calibration Data

It should be noted that in this simple circuit, the supply voltage will fall below the battery voltage before it falls below the $\overline{SLEEP}$ pin threshold, and the battery will be supplying the full 2 mA operating current of the AD7703 until the supply falls below the logic 0 voltage of the $\overline{SLEEP}$ pin. This can cause excessive battery drain if power loss is frequent or the supply voltage falls slowly, for example if there are large reservoir capacitors in the system. In this case, the backup circuit should be designed so that voltage on $\overline{SLEEP}$ falls to 0.8 V before the supply voltage falls below 3.6 V.

DIGITAL INTERFACE

The AD7703's serial communications port allows easy interfacing to industry standard microprocessors. Two different modes of operation are available, optimized for different types of interface.

SYNCHRONOUS SELF-CLOCKING MODE (SSC)

The SSC mode (MODE pin high) allows easy interfacing to serial-parallel conversion circuits in systems with parallel data communication. This mode allows interfacing to 74XX299 Universal Shift registers without any additional decoding. The SSC mode can also be used with microprocessors such as the 68HC11 and 68HC05, which allow an external device to clock their serial port.

Figure 17 shows the timing diagram for the SSC mode. Data is clocked out by an internally generated serial clock. The AD7703 divides each sampling interval into sixteen distinct periods. Eight periods of 64 clock pulses are for analog settling and eight periods of 64 clock pulses are for digital computation. The status of $\overline{CS}$ is polled at the beginning of each digital computation period. If it is low at any of these times then SCLK will become active and the data word currently in the output register will be transmitted, MSB first. After the LSB has been transmitted $\overline{DRDY}$ will go high until the new data word becomes available. If $\overline{CS}$, having been brought low, is taken high again at any time during data transmission, SDATA and SCLK will go three-state after the current bit finishes. If $\overline{CS}$ is subsequently brought low, transmission will resume with the next bit during the subsequent digital computation period. If transmission has not been initiated and completed by the time the next data word is available, $\overline{DRDY}$ will go high for four clock cycles then low again as the new word is loaded into the output register.

A more detailed diagram of the data transmission in the SSC mode is shown in Figure 18. Data bits change on the falling edge of SCLK and are valid on the rising edge of SCLK.

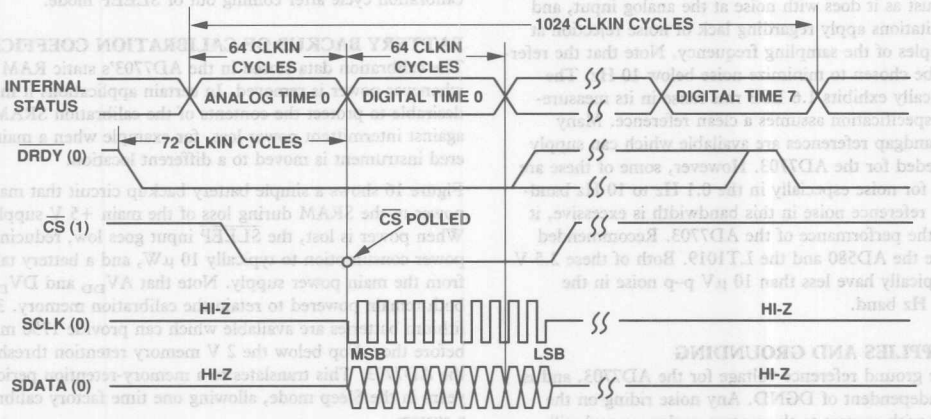

Figure 17. Timing Diagram for SSC Data Transmission Mode

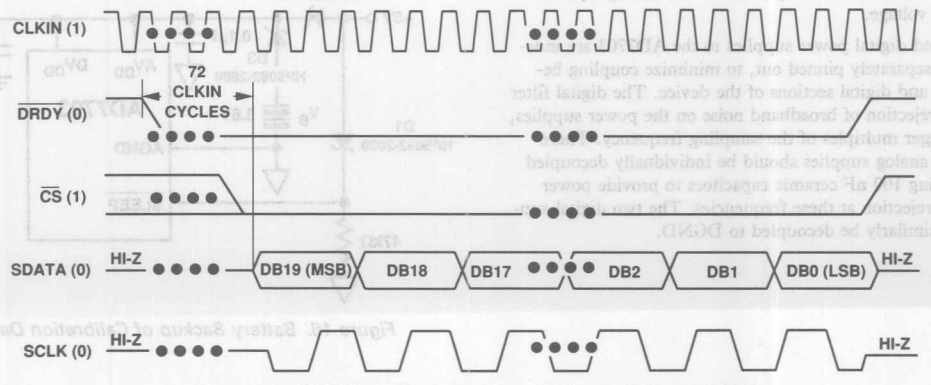

Figure 18. SSC Mode Showing Data Timing Relative to SCLK

SYNCHRONOUS EXTERNAL CLOCK MODE (SEC)

The SEC mode (MODE pin grounded) is designed for direct interface to the synchronous serial ports of industry standard microprocessors such as the 68HC11 and 68HC05. The SEC mode also allows customized interfaces, using I/O port pins, to microprocessors that do not have a direct fit with the AD7703's other mode.

As shown in Figure 19, a falling edge on $\overline{CS}$ enables the serial data output with the MSB initially valid. Subsequent data bits change on the falling edge of an externally supplied SCLK. After the LSB has been transmitted, $\overline{DRDY}$ and SDATA go three-state. If $\overline{CS}$ is low and the AD7703 is still transmitting data when a new data word becomes available, the old data word continues to be transmitted and the new data is lost.

If $\overline{CS}$ is taken high at any time during data transmission, SDATA will go three-state immediately. If $\overline{CS}$ returns low, the AD7703 will continue transmission with the same data bit. If transmission has not been initiated and completed by the time the next data word becomes available, and if $\overline{CS}$ is high, $\overline{DRDY}$ will return high for four clock cycles, then fall as the new word is loaded into the output register.

DIGITAL NOISE AND OUTPUT LOADING

As mentioned earlier, the AD7703 divides its internal timing into two distinct phases, analog sampling and settling and digital computation. In the SSC mode, data is transmitted only during the digital computation periods, to minimize the effects of digital noise on analog performance. In the SEC mode data transmission is externally controlled, so this automatic safeguard does not exist. To compensate, the AD7703 should be synchronized to the digital system clock via CLKIN when used in the SEC mode.

Whatever mode of operation is used, resistive and capacitive loads on digital outputs should be minimized in order to reduce crosstalk between analog and digital portions of the circuit. For this reason connection to low-power CMOS logic such as one of the 4000 series or 74C families is recommended.

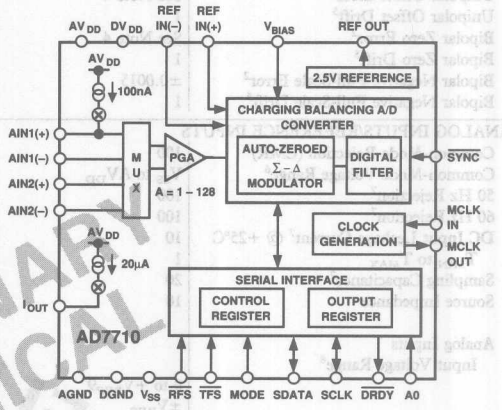
ANALOG DEVICES

LC²MOS Signal Conditioning ADC

AD7710*

FEATURES

Charge Balancing ADC
- 21 Bits No Missing Codes
- ±0.0015% Nonlinearity



Two-Channel Programmable Gain Front End
- Gains from 1 to 128
- Differential Inputs

Low Pass Filter with Programmable Filter Cutoffs
Ability to Read/Write Calibration Coefficients
Bidirectional Microcontroller Serial Interface
Internal/External Reference Option
Single or Dual Supply Operation
Low Power (25 mW typ) with Power Down Mode (50 μW typ)

APPLICATIONS

Weigh Scales
Thermocouples
Process Control
Smart Transmitters
Chromatography

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7710 is a complete analog front end for low frequency measurement applications. The device accepts low level signals directly from a strain gage or transducer and outputs a serial digital word. It employs a sigma-delta conversion technique to realize up to 21 bits of no missing codes performance. The input signal is applied to a proprietary programmable gain front end based around an analog modulator. The modulator output is processed by an on-chip digital filter. The first notch of this digital filter can be programmed via the on-chip control register allowing adjustment of the filter cutoff and settling time.

The part features two differential analog inputs and a differential reference input. Normally, one of the channels will be used as the main channel with the second channel used as an auxiliary input to periodically measure a second voltage. It can be operated from a single supply (by tying the V_{SS} pin to AGND) provided that the input signals on the analog inputs are more positive than −30 mV. By taking the V_{SS} pin negative, the part can convert signals down to $-V_{REF}$ on its inputs. The AD7710 thus performs all signal conditioning and conversion for a single or dual channel system.

The AD7710 is ideal for use in smart, microcontroller based systems. Input channel selection, gain settings and signal polarity can be configured in software using the bidirectional serial port. The AD7710 contains self-calibration, system calibration and background calibration options and also allows the user to read and write the on-chip calibration registers.

CMOS construction ensures low power dissipation and a software programmable power down mode reduces the standby power consumption to only 50 μW typical. The part is available in a 24-pin, 0.3 inch wide, plastic and hermetic dual-in-line package (DIP) as well as a 24-lead small outline (SOIC) package.

PRODUCT HIGHLIGHTS

1. The programmable gain front end allows the AD7710 to accept input signals directly from a strain gage or transducer, removing a considerable amount of signal conditioning.
2. The AD7710 is ideal for microcontroller or DSP processor applications with an on-chip control register which allows control over filter cutoff, input gain, channel selection, signal polarity and calibration modes.
3. The AD7710 allows the user to read and write the on-chip calibration registers. This means that the microcontroller has much greater control over the calibration procedure.
4. No missing codes ensures true, usable, 21-bit dynamic range coupled with excellent ±0.0015% accuracy. The effects of temperature drift are eliminated by on-chip self-calibration, which removes zero scale and full-scale errors.

*Patent pending.

PRELIMINARY TECHNICAL DATA

Positive Supply (AV_{DD})[14]	80	dB typ	
Negative Supply (V_{SS})	90	dB typ	
Power Dissipation			
Normal Mode	40	mW max	AV_{DD} = DV_{DD} = +5 V, V_{SS} = 0 V; Typically 25 mW
Normal Mode	45	mW max	AV_{DD} = DV_{DD} = +5 V, V_{SS} = −5 V; Typically 30 mW
Standby (Power-Down) Mode	100	μW max	AV_{DD} = DV_{DD} = +5 V, V_{SS} = 0 V or −5 V; Typically 50 μW

NOTES

[1]Temperature ranges are as follows: A Version, −40°C to +85°C; S Version −55°C to +125°C.

[2]Applies after calibration at the temperature of interest.

[3]Positive full-scale error applies to both unipolar and bipolar input ranges.

[4]These errors will be of the order of the output noise of the part as shown in Table I.

[5]Recalibration at any temperature or use of the background calibration mode will remove these drift errors. These numbers are guaranteed by design and/or characterization.

[6]This common-mode voltage range is allowed provided that the absolute value of the input voltage does not exceed AV_{DD} +30 mV and V_{SS} −30 mV.

[7]These numbers are guaranteed by design and/or characterization.

[8]The analog inputs present a very high impedance dynamic load which varies with clock frequency and input sample rate. The maximum recommended source resistance is 10 kΩ.

[9]V_{REF} = REF IN(+) − REF IN(−).

[10]Sample tested at +25°C to ensure compliance.

[11]After calibration, if the analog input exceeds positive full scale, the converter will output all 1s. If the analog input is less than negative full scale, then the device will output all 0s.

[12]These calibration and span limits apply provided the absolute voltage on the analog inputs does not exceed V_{DD} or go more negative than V_{SS} − 30 mV. The offset calibration limit applies to both the unipolar zero point and the bipolar zero point.

[13]Measured at dc and applies in the selected passband. PSRR at 50 Hz will exceed 120 dB with filter notches of 10 Hz, 25 Hz or 50 Hz. PSRR at 60 Hz will exceed 120 dB with filter notches of 10 Hz, 30 Hz or 60 Hz.

[14]This number can be improved (to 95 dB typ) by deriving the V_{BIAS} voltage (via Zener diode or reference) from the AV_{DD} supply.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of the specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

TIMING CHARACTERISTICS[1, 2] (DV_{DD} = +5 V ± 10%; AV_{DD} = +5 V or +10 V ± 10% V_{SS} = 0 V or −5 V ±10%; AGND = DGND = 0 V; $f_{CLK\ IN}$ = 10 MHz; Input Logic 0 = 0 V, Logic 1 = DV_{DD} unless otherwise stated.)

t_{36}	20	ns min	Data Valid to SCLK Hold Time

NOTES

[1]Sample tested at +25°C to ensure compliance. All input signals are specified with tr= tf= 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

[2]See Figures 8 to 11.

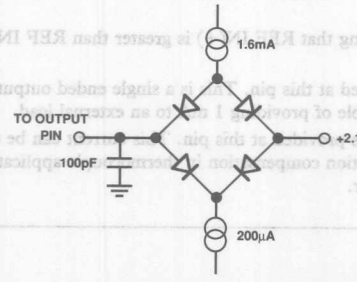
[3]CLK IN duty cycle range is 20% to 80%. CLK IN must be supplied whenever the AD7710 is not in STANDBY mode. If no clock is present in this case, the device can draw higher current than specified and possibly become uncalibrated.

[4]The AD7710 is production tested with $f_{CLK\ IN}$ at 10 MHz. It is guaranteed by characterization to operate at 400 kHz.

[5]Specified using 10% and 90% points on waveform of interest.

[6]These numbers are measured with the load circuit of Figure 1 and defined as the time required for the output to cross 0.8 V or 2.4 V.

[7]These numbers are derived from the measured time taken by the data output to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove effects of charging or discharging the 100 pF capacitor. This means that the times quoted in the timing characteristics are the true bus relinquish times of the part and as such are independent of external bus loading capacitances.



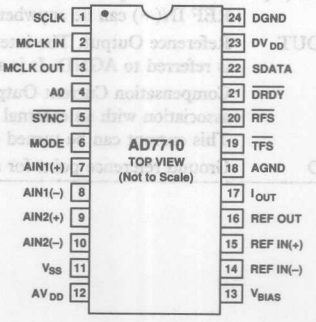


Figure 1. Load Circuit for Access Time and Bus Relinquish Time

PIN CONFIGURATION
DIP and SOIC

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

PIN FUNCTION DESCRIPTION

Pin	Mnemonic	Function
1	SCLK	Serial Clock. Logic Input/Output depending on the status of the MODE pin. When MODE is high, the device is in its self-clocking mode and the SCLK pin provides a serial clock output. This SCLK becomes active when $\overline{RFS}$ or $\overline{TFS}$ goes low and it goes high impedance when either $\overline{RFS}$ or $\overline{TFS}$ returns high or when the device has completed transmission of an output word. When MODE is low, the device is in its external clocking mode and the SCLK pin acts as an input. This input serial clock can be a continuous clock with all data transmitted in a continuous train of pulses. Alternatively, it can be a noncontinuous clock with the information being transmitted to the AD7710 in smaller batches of data.
2	MCLK IN	Master Clock signal for the device. This can be provided in the form of a crystal or external clock. A crystal can be tied across the MCLK IN and MCLK OUT pins. Alternatively, the MCLK IN pin can be driven with a CMOS compatible clock and MCLK OUT left unconnected. The clock input frequency is nominally 10 MHz.
3	MCLK OUT	When the master clock for the device is a crystal, the crystal is connected between MCLK IN and MCLK OUT.
4	A0	Address Input. With this input low, reading and writing to the device is to the control register. With this input high, access is to either the data register or the calibration registers.
5	$\overline{SYNC}$	Logic Input which allows for synchronization of the digital filters when using a number of AD7710s. It resets the nodes of the digital filter.
6	MODE	Logic Input. When this pin is high, the device is in its self-clocking mode; with this pin low, the device is in its external clocking mode.
7	AIN1(+)	Analog Input Channel 1. Positive input of the programmable gain differential analog input. The AIN1(+) input is connected to an output current source which can be used to check that an external transducer has burnt out or gone open circuit. This output current source can be turned on/off via the control register.
8	AIN1(−)	Analog Input Channel 1. Negative input of the programmable gain differential analog input.
9	AIN2(+)	Analog Input Channel 2. Positive input of the programmable gain differential analog input.
10	AIN2(−)	Analog Input Channel 2. Negative input of the programmable gain differential analog input.
11	V_{SS}	Analog Negative Supply, 0 V to −5 V. Tied to AGND for single supply operation. The input voltage on AIN1 or AIN2 should not go > 30 mV negative w.r.t. V_{SS} for correct operation of the device.
12	AV_{DD}	Analog Positive Supply Voltage, +5 V to +10 V.
13	V_{BIAS}	Input Bias Voltage. This input voltage should be set such that $V_{BIAS} + 0.85 \times V_{REF} < AV_{DD}$ and $V_{BIAS} - 0.85 \times V_{REF} > V_{SS}$ where V_{REF} is REF IN(+)− REF IN(−). Ideally, this should be tied halfway between AV_{DD} and V_{SS}. Thus with AV_{DD}=+5 V and V_{SS}=0 V, it can be tied to REF OUT; with AV_{DD} = +5 V and V_{SS} = −5 V, it can be tied to AGND while with AV_{DD} = +10 V, it can be tied to +5 V or to REF OUT.
14	REF IN (−)	Reference Input. The REF IN(−) can lie anywhere between AV_{DD} and V_{SS} provided REF IN(+) is greater than REF IN(−).
15	REF IN (+)	Reference Input. The reference input is differential providing that REF IN(+) is greater than REF IN(−). REF IN(+) can lie anywhere between AV_{DD} and V_{SS}.
16	REF OUT	Reference Output. The internal +2.5 V reference is provided at this pin. This is a single ended output which is referred to AGND. It is a buffered output which is capable of providing 1 mA to an external load.
17	I_{OUT}	Compensation Current Output. A 20 μA constant current is provided at this pin. This current can be used in association with an external thermistor to provide cold junction compensation in thermocouple applications. This current can be turned on or off via the control register.
18	AGND	Ground reference point for analog circuitry.

PRELIMINARY DATA SHEET

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Pin	Mnemonic	Function
19	$\overline{TFS}$	Transmit Frame Synchronization. Active low logic input used to write serial data to the device with serial data expected after the falling edge of this pulse. In the self-clocking mode, the serial clock becomes active after $\overline{TFS}$ goes low. In the self-clocking mode, $\overline{TFS}$ must go low before the first bit of the data word is written to the part.
20	$\overline{RFS}$	Receive Frame Synchronization. Active low logic input used to access serial data from the device. In the self-clocking mode, the SCLK and SDATA lines both become active after $\overline{RFS}$ goes low. In the external clocking mode, the SDATA line becomes active after $\overline{RFS}$ goes low.
21	$\overline{DRDY}$	Logic output. A falling edge indicates that a new output word is available for transmission. The $\overline{DRDY}$ pin will return high upon completion of transmission of a full output word. $\overline{DRDY}$ is also used to indicate when the AD7710 has completed its on-chip calibration sequence.
22	SDATA	Serial Data. Input /Output with serial data being written to either the control register or the calibration registers and serial data being accessed from the control register, calibration registers or the data register. During a read operation, serial data becomes active after $\overline{RFS}$ goes low. During a write operation, valid serial data is expected on the rising edges of SCLK when $\overline{TFS}$ is low.
23	DV_{DD}	Digital Supply Voltage, +5 V. DV_{DD} should never exceed AV_{DD} by more than 0.3 V. If DV_{DD} powers up before AV_{DD} or if DV_{DD} can exceed AV_{DD} by more than 0.3 V at any other time, a Schottky diode should be placed between the two pins.
24	DGND	Ground reference point for digital circuitry.

TERMINOLOGY

INTEGRAL NONLINEARITY

This is the maximum deviation of any code from a straight line passing through the endpoints of the transfer function. The endpoints of the transfer function are zero scale (not to be confused with bipolar zero), a point 0.5 LSB below the first code transition (000 . . . 000 to 000 . . . 001) and full scale, a point 0.5 LSB above the last code transition (111 . . . 110 to 111 . . . 111). The error is expressed as a percentage of full scale.

POSITIVE FULL-SCALE ERROR

Positive Full-Scale Error is the deviation of the last code transition (111 . . . 110 to 111 . . . 111) from the ideal AIN(+) voltage (AIN(−) + V_{REF}/GAIN −3/2 LSBs). It applies to both unipolar and bipolar analog input ranges.

UNIPOLAR OFFSET ERROR

Unipolar Offset Error is the deviation of the first code transition from the ideal AIN(+) voltage is (AIN(−) + 0.5 LSB) when operating in the unipolar mode.

BIPOLAR ZERO ERROR

This is the deviation of the midscale transition (0111 . . . 111 to 1000 . . . 000) from the ideal AIN(+) voltage (AIN(−) −0.5 LSB) when operating in the bipolar mode.

BIPOLAR NEGATIVE FULL-SCALE ERROR

This is the deviation of the first code transition from the ideal AIN(+) voltage (AIN(−) −V_{REF}/GAIN + 0.5 LSB) when operating in the bipolar mode.

POSITIVE FULL-SCALE OVERRANGE

Positive Full-Scale Overrange is the amount of overhead available to handle input voltages on AIN(+) input greater than AIN(−) +V_{REF}/GAIN (for example, noise peaks or excess voltages due to system gain errors in system calibration routines) without introducing errors due to overloading the analog modulator or overflowing the digital filter.

NEGATIVE FULL-SCALE OVERRANGE

This is the amount of overhead available to handle voltages on AIN(+) below AIN(−) −V_{REF}/GAIN without overloading the analog modulator or overflowing the digital filter. Note that the analog input will accept negative voltage peaks even in the unipolar mode provided that AIN(+) is greater than AIN(−) and greater than V_{SS}−30 mV.

OFFSET CALIBRATION RANGE

In the system calibration modes, the AD7710 calibrates its offset with respect to the analog input. The Offset Calibration Range specification defines the range of voltages that the AD7710 can accept and still calibrate offset accurately.

FULL-SCALE CALIBRATION RANGE

This is the range of voltages that the AD7710 can accept in the system calibration mode and still calibrate full scale correctly.

INPUT SPAN

In system calibration schemes, two voltages applied in sequence to the AD7710's analog input define the analog input range. The input span specification defines the minimum and maximum input voltages from zero to full scale that the AD7710 can accept and still calibrate gain accurately.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

CONTROL REGISTER (24 BITS)

A write to the device with the A0 input low writes data to the control register. A read to the device with the A0 input low accesses the contents of the control register.

MD2	MD1	MD0	G2	G1	G0	CH	PD	WL	IO	BO	B/U

FS11	FS10	FS9	FS8	FS7	FS6	FS5	FS4	FS3	FS2	FS1	FS0

Operating Mode

MD2	MD1	MD0	Operating Mode
0	0	0	Normal Mode. This is the normal mode of operation of the device whereby a read to the device with A0 high accesses data from the data register. This is the default condition of these bits after the internal power on reset.
0	0	1	Activate Self-Calibration. This activates self-calibration on the channel selected by CH. This is a one-step calibration sequence, and when complete, the part returns to normal mode. The $\overline{DRDY}$ output indicates when this self-calibration is complete. For this calibration type, the zero scale calibration is done internally on AGND and the full-scale calibration is done internally on V_{REF}.
0	1	0	Activate System Calibration. This activates system calibration on the channel selected by CH. This is a two-step calibration sequence, with the zero scale calibration done first on the selected input channel and $\overline{DRDY}$ indicating when this zero scale calibration is complete. The part returns to normal mode at the end of this first step in the two-step sequence.
0	1	1	Activate System Calibration. This is the second step of the system calibration sequence with full-scale calibration being performed on the selected input channel. Once again, $\overline{DRDY}$ indicates when the full-scale calibration is complete. When this calibration is complete, the part returns to normal mode.
1	0	0	Activate System Offset Calibration. This activates system offset calibration on the channel selected by CH. This is a one-step calibration sequence and, when complete, the part returns to normal mode with $\overline{DRDY}$ indicating when this system offset calibration is complete. For this calibration type, the zero scale calibration is done on the selected input channel and the full-scale calibration is done internally on V_{REF}.
1	0	1	Activate Background Calibration. This activates background calibration on the channel selected by CH. If the background calibration mode is on, then the AD7710 provides continuous self-calibration of the reference and AGND. This calibration takes place as part of the conversion sequence, extending the conversion time and reducing the word rate by a factor of six. Its major advantage is that the user does not have to worry about recalibrating the device when there is a change in the ambient temperature. In this mode, AGND and V_{REF}, as well as the analog input voltage, are continuously monitored and the calibration registers of the device are automatically updated, if necessary.
1	1	0	Read/Write Zero Scale Calibration Coefficients. A read to the device with A0 high accesses the contents of the zero scale calibration coefficients of the channel selected by CH. A write to the device with A0 high writes data to the zero scale calibration coefficients of the channel selected by CH. The word length for reading and writing these coefficients is 24 bits, regardless of the status of the WL bit of the control register.
1	1	1	Read/Write Full-Scale Calibration Coefficients. A read to the device with A0 high accesses the contents of the full-scale calibration coefficients of the channel selected by CH. A write to the device with A0 high writes data to the full-scale calibration coefficients of the channel selected by CH. The word length for reading and writing these coefficients is 24 bits, regardless of the status of the WL bit of the control register.

FILTER SECTION (FS11–FS0)

The on-chip digital filter provides a $Sinc^3$ (or $(Sinx/x)^3$ filter response. The 12 bits of data programmed into these bits determine the filter cutoff frequency, the position of the first notch of the filter and the data rate for the part. In association with the gain selection, it also determines the output noise (and hence the effective resolution) of the device.

The first notch of the filter occurs at a frequency determined by the relationship: filter first notch frequency = $(f_{CLK\ IN}/512)/$ *code* where *code* is the decimal equivalent of the code in bits FS0 to FS11 and is in the range 19 to 2,000. With the nominal $f_{CLK\ IN}$ of 10 MHz, this results in a first notch frequency range from 9.76 Hz to 1.028 kHz. To ensure correct operation of the AD7710, the value of the code loaded to these bits must be within this range. Failure to do this will result in unspecified operation of the device.

Changing the filter notch frequency, as well as the selected gain, impacts resolution. Tables I and II and Figure 2 show the effect of the filter notch frequency and gain on the effective resolution of the AD7710. The output data rate (or effective conversion time) for the device is equal to the frequency selected for the first notch of the filter. For example, if the first notch of the filter is selected at 50 Hz, then a new word is available at a 50 Hz rate or every 20 ms. If the first notch is at 1 kHz, a new word is available every 1 ms.

The settling time of the filter to a full-scale step input change is worst case 4× the data rate. For example, with the first filter notch at 50 Hz, the settling time of the filter to a full-scale step input change is 80 ms max. If the first notch is at 1 kHz, the settling time of the filter to a full-scale input step is 4 ms max

The −3 dB frequency is determined by the programmed first notch frequency according to the relationship: filter −3 dB frequency = 0.262 × first notch frequency.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Table I shows the output rms noise for some typical notch and −3 dB frequencies. The numbers given are for the bipolar input ranges with a V_{REF} of +2.5 V. The numbers in Table I are guaranteed by a combination of testing, characterization and design. The output noise from the part comes from two sources, the quantization noise from the analog-to-digital conversion process and device noise. Device noise is independent of gain and essentially flat across the frequency spectrum. Quantization noise is ratiometric to the input full-scale (and hence gain) and its frequency response is shaped by the modulator.

Looking at the table below, as the cutoff frequency increases the output noise increases because more of the quantization noise of the part comes through to the output and, hence, the output noise increases with increasing −3 dB frequencies. For the lower notch settings, the output noise is dominated by the device noise and, hence, altering the gain has little effect on the output noise. At higher notch frequencies, the quantization noise dominates the output noise and, in this case, the output noise tends to decrease with increasing gain.

Since the output noise comes from two sources, the effective resolution of the device (i.e., the ratio of the output rms noise to the input full scale) does not remain constant with increasing gain or with increasing bandwidth. Table II shows the same table as Table I except that the output is now expressed in terms of effective resolution (the magnitude of the rms noise with respect to 2 × V_{REF}/GAIN, i.e., the input full scale). It is possible to do post filtering on the device to improve the output data rate for a given −3 dB frequency and also to further reduce the output noise (see Digital Filtering section).

Table I. Output Noise vs. Gain and First Notch Frequency

First Notch of Filter and O/P Data Rate[1]	Output RMS Noise (μV) −3 dB Frequency	Gain of 1	Gain of 2	Gain of 4	Gain of 8	Gain of 16	Gain of 32	Gain of 64	Gain of 128
10 Hz[2]	2.62 Hz	1.7	0.84	0.60	0.42	0.42	0.42	0.42	0.42
25Hz[2]	6.55 Hz	3.4	1.7	1.2	0.60	0.60	0.60	0.60	0.60
30 Hz[2]	7.86 Hz	3.4	2.4	1.2	0.84	0.84	0.60	0.60	0.60
50 Hz[2]	13.1 Hz	9.5	4.8	2.4	1.7	1.2	0.84	0.84	0.84
60 Hz[2]	15.72 Hz	13.5	6.7	3.4	1.7	1.2	1.2	0.84	0.84
100 Hz[3]	26.2 Hz	54	27	13.5	6.7	3.4	1.7	1.7	1.2
250 Hz[3]	65.5 Hz	432	216	108	54	27	13.5	6.7	4.8
500 Hz[3]	131 Hz	2.4 × 10^3	1.2 × 10^3	610	305	153	76	38	19
1 kHz[3]	262 Hz	13.8 × 10^3	6.9 × 10^3	3.4 × 10^3	1.7 × 10^3	863	432	216	108

NOTES
[1]The default condition (after the internal power-on reset) for the first notch of filter is 60 Hz.
[2]For these filter notch frequencies, the output rms noise is primarily independent of the value of the reference voltage. Therefore, increasing the reference voltage will give an increase in the effective resolution of the device (i.e., the ratio of the rms noise to the input full scale is increased since the output rms noise remains constant as the input full-scale increases).
[3]For these filter notch frequencies, the output rms noise is proportional to the value of the reference voltage.

Table II. Effective Resolution vs. Gain and First Notch Frequency

First Notch of Filter and O/P Data Rate[1]	Effective Resolution[1] (Bits) −3 dB Frequency	Gain of 1	Gain of 2	Gain of 4	Gain of 8	Gain of 16	Gain of 32	Gain of 64	Gain of 128
10 Hz	2.62 Hz	21.5	21.5	21	20.5	19.5	18.5	17.5	16.5
25 Hz	6.55 Hz	20.5	20.5	20	20	19	18	17	16
30 Hz	7.86 Hz	20.5	20	20	19.5	18.5	18	17	16
50 Hz	13.1 Hz	19	19	19	18.5	18	17.5	16.5	15.5
60 Hz	15.72 Hz	18.5	18.5	18.5	18.5	18	17	16.5	15.5
100 Hz	26.2 Hz	16.5	16.5	16.5	16.5	16.5	16.5	15.5	15
250 Hz	65.5 Hz	13.5	13.5	13.5	13.5	13.5	13.5	13.5	13
500 Hz	131 Hz	11	11	11	11	11	11	11	11
1 kHz	262 Hz	8.5	8.5	8.5	8.5	8.5	8.5	8.5	8.5

NOTE
[1]Effective resolution is defined as the magnitude of the output rms noise to the input full scale (i.e., 2 × V_{REF}/GAIN). The above table applies for a V_{REF} of +2.5 V and resolution numbers are rounded to the nearest 0.5 LSB.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Figure 2 gives similar information to that outlined in Table I. In this plot, the output rms noise is shown for the full range of available cutoff frequencies rather than for some typical cutoff frequencies as in Tables I and II. The numbers given in this plot are typical values.

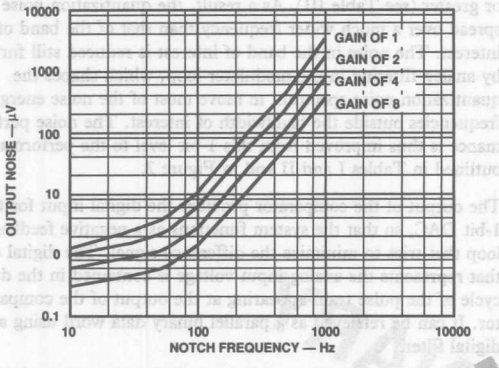

Figure 2a. Plot of Output Noise vs. Gain and Notch Frequency (Gains of 1 to 8)

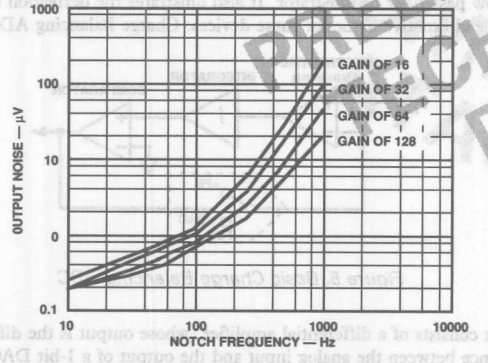

Figure 2b. Plot of Output Noise vs. Gain and Notch Frequency (Gains of 16 to 128)

CIRCUIT DESCRIPTION

The AD7710 is a sigma-delta A/D converter with on-chip digital filtering, intended for the measurement of wide dynamic range, low frequency signals such as those in weigh scale, industrial control or process control applications. It contains a sigma-delta (or charge balancing) ADC, a calibration microcontroller with on-chip static RAM, a clock oscillator, a digital filter and a bidirectional serial communications port.

The part contains two programmable gain differential analog input channels. The gain range is from 1 to 128 allowing the part to accept unipolar signals of between 0 to +20 mV and 0 to +2.5 V or bipolar signals in the range from ±20 mV to ±2.5 V when the reference input voltage equals +2.5 V. The input signal to the selected analog input channel is continuously sampled at a rate determined by the frequency of the master clock, CLK IN, and the selected gain (see Table III). A charge balancing A/D converter (Sigma-Delta Modulator) converts the sampled signal into a digital pulse train whose duty cycle contains the digital information. The programmable gain function on the analog input is also incorporated in this sigma-delta modulator with the input sampling frequency being modified to give the higher gains. A sinc^3 digital low pass filter processes the output of the sigma-delta modulator and updates the output register at a rate determined by the first notch frequency of this filter. The output data can be read from the serial port randomly or periodically at any rate up to the output register update rate. The first notch of this digital filter (and hence its −3 dB frequency) can be programmed via an on-chip control register. The programmable range for this first notch frequency is from 9.76 Hz to 1.028 kHz, giving a programmable range for the −3 dB frequency of 2.58 Hz to 269 Hz.

The basic connection diagram for the part is shown in Figure 3. This shows the AD7710 in the external clocking mode with both the AV_{DD} and DV_{DD} pins of the AD7710 being driven from the analog +5 V supply. Some applications will have separate supplies for both AV_{DD} and DV_{DD} and, in some of these cases, the analog supply will exceed the +5 V digital supply (see Power Supplies and Grounding section).

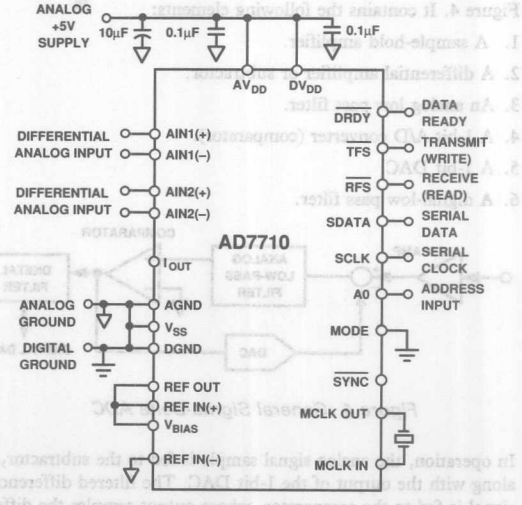

Figure 3. Basic Connection Diagram

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

The AD7710 provides a number of calibration options which can be programmed via the on-chip control register. A calibration cycle may be initiated at any time by writing to this control register. The part can perform self-calibration using the on-chip calibration microcontroller and SRAM to store calibration parameters. Other system components may also be included in the calibration loop to remove offset and gain errors in the input channel using the system calibration mode. Another option is a background calibration mode where the part continuously performs self-calibration and updates the calibration coefficients. Once the part is in this mode, the user does not have to worry about issuing periodic calibration commands to the device or ask the device to recalibrate when there is a change in the ambient temperature or power supply voltage.

The AD7710 gives the user access to the on-chip calibration registers allowing the microprocessor to read the device's calibration coefficients and also to write its own calibration coefficients to the part. This gives the microprocessor much greater control over the AD7710's calibration procedure. It also means that the user can verify that the device has performed its calibration correctly by comparing the coefficients after calibration with prestored values in E^2PROM.

The AD7710 can be operated in single supply systems provided that the analog input voltage does not go more negative than 30 mV. For larger bipolar signals, a V_{SS} of −5 V is required by the part. For battery operation, the AD7710 also offers a software programmable standby mode that reduces idle power consumption to typically 50 μW.

THEORY OF OPERATION

The general block diagram of a sigma-delta ADC is shown in Figure 4. It contains the following elements:

1. A sample-hold amplifier.
2. A differential amplifier or subtractor.
3. An analog low pass filter.
4. A 1-bit A/D converter (comparator).
5. A 1-bit DAC.
6. A digital-low pass filter.

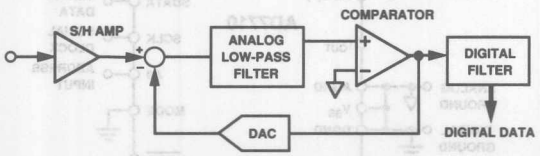

Figure 4. General Sigma-Delta ADC

In operation, the analog signal sample is fed to the subtractor, along with the output of the 1-bit DAC. The filtered difference signal is fed to the comparator, whose output samples the difference signal at a frequency many times that of the analog signal sampling frequency (oversampling).

Oversampling is fundamental to the operation of sigma-delta ADCs. Using the quantization noise formula for an ADC:

$$SNR = (6.02 \times number\ of\ bits + 1.76)\ dB,$$

a 1-bit ADC or comparator yields an SNR of 7.78 dB.

The AD7710 samples the input signal at a frequency of 20 kHz or greater (see Table III). As a result, the quantization noise is spread over a much wider frequency than that of the band of interest. The noise in the band of interest is reduced still further by analog filtering in the modulator loop, which shapes the quantization noise spectrum to move most of the noise energy to frequencies outside the bandwidth of interest. The noise performance is thus improved from this 1-bit level to the performance outlined in Tables I and II and in Figure 2.

The output of the comparator provides the digital input for the 1-bit DAC, so that the system functions as a negative feedback loop that tries to minimize the difference signal. The digital data that represents the analog input voltage is contained in the duty cycle of the pulse train appearing at the output of the comparator. It can be retrieved as a parallel binary data word using a digital filter.

Sigma-delta ADCs are generally described by the order of the analog low pass filter. A simple example of a first order sigma-delta ADC is shown in Figure 5. This contains only a first order low pass filter or integrator. It also illustrates the derivation of the alternative name for these devices: Charge Balancing ADCs.

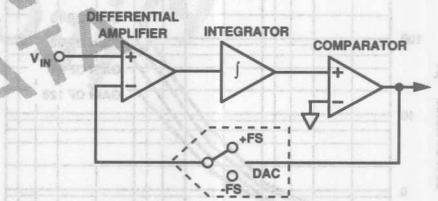

Figure 5. Basic Charge Balancing ADC

It consists of a differential amplifier (whose output is the difference between the analog input and the output of a 1-bit DAC), an integrator and a comparator. The term, charge balancing, comes from the fact that this system is a negative feedback loop that tries to keep the nett charge on the integrator capacitor at zero, by balancing charge injected by the input voltage with charge injected by the 1-bit DAC. When the analog input is zero, the only contribution to the integrator output comes from the 1-bit DAC. For the nett charge on the integrator capacitor to be zero, the DAC output must spend half its time at +FS and half its time at −FS. Assuming ideal components, the duty cycle of the comparator will be 50%.

When a positive analog input is applied, the output of the 1-bit DAC must spend a larger proportion of the time at +FS, so the duty cycle of the comparator increases. When a negative input voltage is applied, the duty cycle decreases.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

digital filter that provides a rolling average of the sampled output. After power up or if there is a step change in the input voltage, there is a settling time that must elapse before valid data is obtained.

Input Sample Rate

The modulator sample frequency for the device remains at $f_{CLK\ IN}/512$ (20 kHz @ $f_{CLK\ IN}$ = 10 MHz) regardless of the selected gain. However, gains greater than ×1 are achieved by a combination of multiple input samples per modulator cycle and a scaling of the ratio of reference capacitor to input capacitor. As a result of the multiple sampling, the input sample rate of the device varies with the selected gain (see Table III). The effective input impedance is $1/C \cdot f_S$ where C is the input sampling capacitance and f_S is the input sample rate.

Table III. Input Sampling Frequency vs. Gain

Gain	Input Sampling Frequency (f_S)
1	$f_{CLK\ IN}/512$ (20 kHz @ $f_{CLK\ IN}$ = 10 MHz)
2	$2 \times f_{CLK\ IN}/512$ (40 kHz @ $f_{CLK\ IN}$ = 10 MHz)
4	$4 \times f_{CLK\ IN}/512$ (80 kHz @ $f_{CLK\ IN}$ = 10 MHz)
8	$4 \times f_{CLK\ IN}/512$ (160 kHz @ $f_{CLK\ IN}$ = 10 MHz)
16	$4 \times f_{CLK\ IN}/512$ (160 kHz @ $f_{CLK\ IN}$ = 10 MHz)
32	$4 \times f_{CLK\ IN}/512$ (160 kHz @ $f_{CLK\ IN}$ = 10 MHz)
64	$4 \times f_{CLK\ IN}/512$ (160 kHz @ $f_{CLK\ IN}$ = 10 MHz)
128	$4 \times f_{CLK\ IN}/512$ (160 kHz @ $f_{CLK\ IN}$ = 10 MHz)

DIGITAL FILTERING

The AD7710's digital filter behaves like a similar analog filter, with a few minor differences.

First, since digital filtering occurs after the A-to-D conversion process, it can remove noise injected during the conversion process. Analog filtering cannot do this.

On the other hand, analog filtering can remove noise superimposed on the analog signal before it reaches the ADC. Digital filtering cannot do this and noise peaks riding on signals near full scale have the potential to saturate the analog modulator and digital filter, even though the average value of the signal is within limits. To alleviate this problem, the AD7710 has overrange headroom built into the sigma-delta modulator and digital filter which allows overrange excursions of 5% above the analog input range. If noise signals are larger than this, consideration should be given to analog input filtering, or to reducing the input channel voltage so that its full scale is half that of the analog input channel full scale. This will provide an overrange capability greater than 100% at the expense of reducing the dynamic range by 1 bit (50%).

Filter Characteristics

The cutoff frequency of the digital filter is determined by the value loaded to bits FS0 to FS11 in the control register. At the maximum clock frequency of 10 MHz, the minimum cutoff frequency of the filter is 2.58 Hz while the maximum programmable cutoff frequency is 269 Hz.

quency of 2.62 Hz which corresponds to a first filter notch frequency of 10 Hz. This is a $(\sin x/x)^3$ response (also called sinc^3) that provides >100 dB of 50 Hz and 60 Hz rejection. Programming a different cutoff frequency via FS0–FS11 does not alter the profile of the filter response, it changes the frequency of the notches as outlined in the Control Register section.

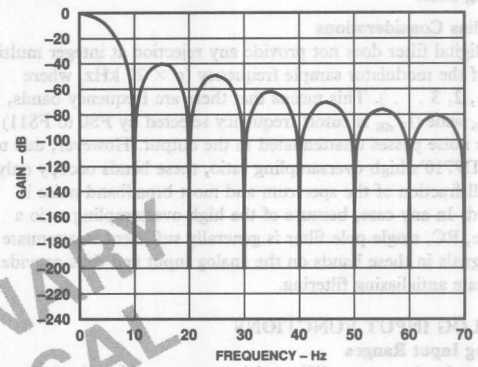

Figure 6. Frequency Response of AD7710 Filter

Post Filtering

The on-chip modulator provides samples at a 20 kHz output rate. The on-chip digital filter decimates these samples to provide data at an output rate which corresponds to the programmed first notch frequency of the filter. Since the output data rate exceeds the Nyquist criterion, the output rate for a given bandwidth will satisfy most application requirements. However, there may be some applications which require a higher data rate for a given bandwidth and noise performance. Applications which need this higher data rate will require some post filtering following the digital filter of the AD7710.

For example, if the required bandwidth is 7.86 Hz but the required update rate is 100 Hz, the data can be taken from the AD7710 at the 100 Hz rate giving a −3 dB bandwidth of 26.2 Hz. Post filtering can be applied to this to reduce the bandwidth and output noise, to the 7.86 Hz bandwidth level, while maintaining an output rate of 100 Hz.

Since the AD7710 contains this on-chip, low pass filtering, there is a settling time associated with step function inputs, and data on the output will be invalid after a step change until the settling time has elapsed. The settling time depends upon the notch frequency chosen for the filter. The output data rate equates to this filter notch frequency and the settling time of the filter to a full-scale step input is 4 times the output data period. In applications using both input channels, the settling time of the filter must be allowed to elapse before data from the second channel is accessed.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Post filtering can also be used to reduce the output noise from the device for bandwidths below 2.62 Hz. At a gain of 128, the output rms noise is 420 nV. This is essentially device noise or white noise, and since the input is chopped, the noise has a flat frequency response. By reducing the bandwidth below 2.62 Hz, the noise in the resultant passband can be reduced. A reduction in bandwidth by a factor of 2 results in a $\sqrt{2}$ reduction in the output rms noise. This additional filtering will result in a longer settling time.

Antialias Considerations

The digital filter does not provide any rejection at integer multiples of the modulator sample frequency (n × 20 kHz, where n = 1, 2, 3 . . .). This means that there are frequency bands, $\pm f_{3\ dB}$ wide ($f_{3\ dB}$ is cutoff frequency selected by FS0 to FS11) where noise passes unattenuated to the output. However, due to the AD7710's high oversampling ratio, these bands occupy only a small fraction of the spectrum and most broadband noise is filtered. In any case, because of the high oversampling ratio a simple, RC, single pole filter is generally sufficient to attenuate the signals in these bands on the analog input and thus provide adequate antialiasing filtering.

ANALOG INPUT FUNCTIONS

Analog Input Ranges

Both analog inputs are differential, programmable gain, input channels which can handle either unipolar or bipolar input signals. The common-mode range of these inputs is from V_{SS} to AV_{DD} provided that the absolute value of the analog input voltage lies between V_{SS}−30 mV and AV_{DD}+30 mV.

The input sample rate for the part varies as per Table III and the input sampling capacitance is 15 pF typical. The effective input impedance is $1/C \cdot f_S$ and this results in a maximum allowable source impedance of whatever is driving the analog input of 10 kΩ to ensure correct charging of the sampling capacitor.

The dc input leakage current is 10 pA maximum at +25°C. This results in a dc offset voltage developed across the source impedance. However, this dc offset effect can be compensated for by a combination of the differential input capability of the part and its system calibration mode.

Burn-Out Current

The AIN1(+) input of the AD7710 contains a 100 nA current source which can be turned on/off via the control register. This current source can be used in checking that a transducer has not burnt out or gone open circuit before attempting to take measurements on that channel. If the current is turned on and allowed flow into the transducer and a measurement of the input voltage on the AIN1 input is taken, it can indicate that the transducer is not functioning correctly. For normal operation, this burn-out current is turned off by writing a 0 to the BO bit in the control register.

Output Compensation Current

The AD7710 also contains a feature which can enable the user to implement cold junction compensation in thermocouple applications. This can be achieved using the output compensation current from the I_{OUT} pin of the device. Once again, this current can be turned on/off via the control register. Writing a 1 to the IO bit of the control register enables this compensation current.

The compensation current provides a 20 μA constant current source which can be used in association with a thermistor or a diode to provide cold junction compensation. A common method of generating cold junction compensation is to use a temperature dependent current flowing through a fixed resistor to provide a voltage that is equal to the voltage developed across the cold junction at any temperature in the expected ambient range. In this case, the temperature coefficient of the compensation current is so low compared with the temperature coefficient of the thermistor that it can be considered constant with temperature. The temperature variation is then provided by the variation of the thermistor's resistance with temperature.

Bipolar/Unipolar Inputs

The two analog inputs on the AD7710 can accept either unipolar or bipolar input voltage ranges. Bipolar or unipolar options are chosen by programming the B/U bit of the control register. This programs both channels for either unipolar or bipolar operation. Programming the part for either unipolar or bipolar operation does not change any of the input signal conditioning; it simply changes the data output coding.

The input channels are differential and, as a result, the voltage to which the unipolar and bipolar signals are referenced is the voltage on the AIN(−) input. For example, if AIN(−) is +1.25 V and the AD7710 is configured for unipolar operation with a gain of 1 and a V_{REF} of +2.5 V, the input voltage range on the AIN(+) input is +1.25 V to +3.75 V. If AIN(−) is +1.25 V and the AD7710 is configured for bipolar mode with a gain of 1 and a V_{REF} of +2.5 V, the analog input range on the AIN(+) input is −1.25 V to +3.75 V.

REFERENCE INPUT/OUTPUT

The AD7710 contains a temperature compensated +2.5 V reference which has an initial tolerance of ±25 mV. This reference voltage is provided at the REF OUT pin and it can be used as the reference voltage for the part by connecting the REF OUT pin to the REF IN(+) pin. This REF OUT pin is a single-ended output, referenced to AGND, which is capable of providing up to 1 mA to an external load. In applications where REF OUT is connected directly to REF IN(+), REF IN(−) should be tied to AGND to provide the nominal +2.5 V reference for the AD7710.

The reference inputs of the AD7710, REF IN(+) and REF IN(−), provide a differential reference input capability. The common-mode range for these differential inputs is from V_{SS} to AV_{DD}. The nominal differential voltage, V_{REF} (REF IN(+) −REF IN(−)), is +2.5 V for specified operation, but the reference voltage can go to +5 V with no degradation in performance provided that the absolute value of REF IN(+) and REF IN(−) does not exceed its AV_{DD} and V_{SS} limits. REF IN(+) must always be greater than REF IN(−) for correct operation of the AD7710.

Both reference inputs provide a high impedance, dynamic load similar to the analog inputs. The maximum dc input leakage current is 10 pA (±1 μA over temperature) and source resistances will result in gain errors on the part. The reference inputs are switched capacitor inputs with the input capacitance dependent upon the selected gain. For gains of 1 to 8 the input capacitance is 20 pF; for a gain of 16 it is 10 pF; for a gain of 32 it is 5 pF; for a gain of 64 it is 2.5 pF; and for a gain of 128 it is 1.25 pF.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

The digital filter of the AD7710 removes noise from the reference input just as it does with the analog input, and the same limitations apply regarding lack of noise rejection at integer multiples of the sampling frequency. The output noise performance outlined in Tables I and II assumes a clean reference. If the reference noise in the bandwidth of interest is excessive, it can degrade the performance of the AD7710. Figure 7 shows the noise performance of the AD7710's on-board reference.

Figure 7. AD7710 Reference Output Noise

V_{BIAS} Input

The V_{BIAS} input determines at what voltage the internal analog circuitry is biased. It essentially provides the return path for analog currents flowing in the modulator and, as such, it should be driven from a low impedance point to minimize errors.

For maximum internal headroom, the V_{BIAS} voltage should be set halfway between AV_{DD} and V_{SS}. The difference between AV_{DD} and (V_{BIAS} + 0.85 × V_{REF}) determines the amount of headroom the circuit has at the upper end, while the difference between V_{SS} and (V_{BIAS} −0.85 × V_{REF}) determines the amount of headroom the circuit has at the lower end. Care should be taken in choosing a V_{BIAS} voltage to ensure that V_{BIAS} ±0.85 × V_{REF} does not exceed the AV_{DD} and V_{SS} limits. For example, with AV_{DD} = +4.75 V, V_{SS} = 0 V and V_{REF} = +2.5 V, the allowable range for the V_{BIAS} voltage is +2.125 V to +2.625 V. With AV_{DD} = +9.5 V, V_{SS} = 0 V and V_{REF} = +5 V, the range for V_{BIAS} is +4.25 V to +5.25 V. With AV_{DD} = +4.75 V, V_{SS} = −4.75 V and V_{REF} = +2.5 V, the V_{BIAS} range is −2.625 V to +2.625 V.

USING THE AD7710

SYSTEM DESIGN CONSIDERATIONS

The AD7710 operates differently from successive approximation ADCs or integrating ADCs. Since it samples the signal continuously, like a tracking ADC, there is no need for a start convert command. The output register is updated at a rate determined by the first notch of the filter and the output can be read at any time, either synchronously or asynchronously.

Clocking

The AD7710 requires a master clock input, which may be an external TTL/CMOS compatible clock signal applied to the MCLK IN pin with the MCLK OUT pin left unconnected. Alternatively, a crystal of the correct frequency can be connected between MCLK IN and MCLK OUT, in which case the clock circuit will function as a crystal controlled oscillator. For lower clock frequencies, a ceramic resonator may be used instead of the crystal. For these lower frequency oscillators, external capacitors may be required on either the ceramic resonator or on the crystal.

The input sampling frequency, the modulator sampling frequency, the −3 dB frequency, output update rate and calibration time are all directly related to the master clock frequency, $f_{CLK\ IN}$. Reducing the master clock frequency by a factor of 2 will halve the above frequencies and update rate and will double the calibration time.

The current drawn from the DV_{DD} power supply is also directly related to $f_{CLK\ IN}$. Reducing $f_{CLK\ IN}$ by a factor of 2 will halve the DV_{DD} current but will not affect the current drawn from the AV_{DD} power supply.

System Synchronization

If multiple AD7710s are operated from a common master clock, they can be synchronized to update their output registers simultaneously. A falling edge on the $\overline{SYNC}$ input resets the filter and places the AD7710 into a consistent, known state. A common signal to the AD7710s' $\overline{SYNC}$ inputs will synchronize their operation. This would normally be done after each AD7710 has performed its own calibration or has had calibration coefficients loaded to it.

ACCURACY

Sigma-delta ADCs, like VFCs and other integrating ADCs, do not contain any source of nonmonotonicity and inherently offer no missing codes performance. The AD7710 achieves excellent linearity by the use of high quality, on-chip silicon dioxide capacitors, which have a very low capacitance/voltage coefficient. The device also achieves low input drift through the use of chopper stabilized techniques in its input stage. To ensure excellent performance over time and temperature, the AD7710 uses digital calibration techniques which minimize offset and gain error.

Autocalibration

Autocalibration on the AD7710 removes offset and gain errors from the device. A calibration routine should be initiated on the device whenever there is a change in the ambient operating temperature or supply voltage. It should also be initiated if there is a change in the selected channel, gain, filter notch or bipolar/unipolar input range. However, if the AD7710 is in its background calibration mode, the above changes are all automatically taken care of (after the settling time of the filter has been allowed for).

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

modulator output for two different input conditions. These are "zero scale" and "full-scale" points. With these readings, the microcontroller can calculate the gain slope for the input to output transfer function of the converter. Internally, the part works with a resolution of 33 bits to determine its conversion result of either 16 bits or 24 bits.

Self-Calibration

In the self-calibration mode with a unipolar input range, the zero scale point used in determining the calibration coefficients is AGND and the full-scale point is V_{REF}. The zero scale coefficient is determined by converting an internal AGND node. The full-scale coefficient is determined from the span between this AGND conversion and a conversion on an internal V_{REF} node. The self-calibration mode is invoked by writing the appropriate values (0, 0, 1) to the MD2, MD1 and MD0 bits of the control register. In this calibration mode, the AGND node is switched in to the modulator first and a conversion is performed; the V_{REF} node is then switched in and another conversion is performed. When the calibration sequence is complete, the calibration coefficients updated and the filter resettled to the analog input voltage, the $\overline{DRDY}$ output goes low.

For bipolar input ranges in the self-calibrating mode, the sequence is very similar to that just outlined. In this case, the two points which the AD7710 calibrates are midscale (bipolar zero) and positive full scale.

System Calibration

System calibration allows the AD7710 to compensate for system gain and offset errors as well as its own internal errors. System calibration performs the same slope factor calculations as self-calibration but uses voltage values presented by the system to the AIN inputs for the zero and full-scale points. System calibration is a two-step process. The zero scale point must be presented to the converter first. It must be applied to the converter before the calibration step is initiated and remain stable until the step is complete. System calibration is initiated by writing the appropriate values (0, 1, 0) to the MD2, MD1 and MD0 bits of the control register. The $\overline{DRDY}$ output from the device will signal when the step is complete by going low. After the zero scale point is calibrated, the full-scale point is applied and the second step of the calibration process is initiated by again writing the appropriate values (0, 1, 1) to MD2, MD1 and MD0. Again the full-scale voltage must be set up before the calibration is initiated and it must remain stable throughout the calibration step. $\overline{DRDY}$ goes low at the end of this second step to indicate that the system calibration is complete. In the unipolar mode, the system calibration is performed between the two endpoints of the transfer function; in the bipolar mode, it is performed between midscale and positive full scale.

This two-step system calibration mode offers another feature. After the sequence has been completed, additional offset calibrations can be performed by themselves to adjust the zero reference point to a new system zero reference value. This is achieved by performing the first step of the system calibration sequence (by writing 0, 1, 0 to MD2, MD1, MD0). This will adjust the zero scale or offset point but will not change the slope factor from what was set during a full system calibration sequence.

[illegible] the system is presented to the AIN input of the converter. System offset calibration is initiated by writing 1, 0, 0 to MD2, MD1, MD0. The system zero scale coefficient is determined by converting the voltage applied to the AIN input while the full-scale coefficient is determined from the span between this AIN conversion and a conversion on an internal V_{REF} node. The zero scale point should be applied to the AIN input for the duration of the calibration sequence. This is a one-step calibration sequence with $\overline{DRDY}$ going low when the sequence is completed. In the unipolar mode, the system offset calibration is performed between the two endpoints of the transfer function; in the bipolar mode, it is performed between midscale and positive full scale.

Background Calibration

The AD7710 also offers a background calibration mode where the part interleaves its calibration procedure with its normal conversion sequence. In the background calibration mode, the same nodes are used as the calibration points as are used in the self-calibration mode, i.e., AGND and V_{REF}. The background calibration mode is invoked by writing 1, 0, 1 to MD2, MD1, MD0 of the control register. When invoked, the background calibration mode reduces the output data rate of the AD7710 by a factor of six. Its advantage is that the part is continually performing calibration and automatically updating its calibration coefficients. As a result, the effects of temperature drift, supply sensitivity and time drift on zero and full-scale errors are automatically removed. When the background calibration mode is turned on, the part will remain in this mode until bits MD2, MD1 and MD0 of the control register are changed.

Table IV summarizes the calibration modes and the calibration points associated with them.

Span and Offset Limits

Whenever a system calibration mode is used, there are limits on the amount of offset and span which can be accommodated. The range of input span in both the unipolar and bipolar modes has a minimum value of $0.8 \times V_{REF}/GAIN$ and a maximum value of $2.1 \times V_{REF}/GAIN$.

The amount of offset which can be accommodated depends on whether the unipolar or bipolar mode is being used. In unipolar mode, the system calibration modes can handle a maximum offset of $0.25 \times V_{REF}/GAIN$ and a minimum offset of $-(1.05 \times V_{REF}/GAIN)$. This offset range is limited by the requirement that the positive full-scale calibration limit is $\leq 1.05 \times V_{REF}/GAIN$. Thus, the maximum offset ($0.25 \times V_{REF}/GAIN$) plus the minimum span ($0.8 \times V_{REF}/GAIN$) cannot exceed $1.05 \times V_{REF}/GAIN$.

In the bipolar mode, the system offset calibration range is restricted to $\pm 0.65 \times V_{REF}/GAIN$. The span range of the converter in bipolar mode is equidistant around the voltage used for the zero scale point. Therefore, the maximum offset $\pm(0.65 \times V_{REF}/GAIN)$ plus half the minimum span $\pm(0.4 \times V_{REF}/GAIN)$ must be less than $\pm(1.05 \times V_{REF}/GAIN)$. If the span is set to $2 \times V_{REF}/GAIN$, the offset span cannot move more than $\pm(0.05 \times V_{REF}/GAIN)$ before the endpoints of the transfer function exceed the input overrange limits $\pm(1.05 \times V_{REF}/GAIN)$.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Cal Type	MD2, MD1, MD0	Zero Scale Cal	Full-Scale Cal	Sequence
Self-Cal	0, 0, 1	AGND	V_{REF}	One Step
System Cal	0, 1, 0	AIN		Two Step
System Cal	0, 1, 1		AIN	Two Step
System Offset Cal	1, 0, 0	AIN	V_{REF}	One Step
Background Cal	1, 0, 1	AGND	V_{REF}	One Step

POWER-UP AND CALIBRATION

On power-up, the AD7710 performs an internal reset which sets the contents of the control register to a known state. However, to ensure correct calibration for the device, a calibration routine should be performed after power-up.

The power dissipation and temperature drift of the AD7710 are low and no warm up time is required before the initial calibration is performed. However, if an external reference is being used, this reference must have stabilized before calibration is initiated.

Drift Considerations

The AD7710 uses chopper stabilization techniques to minimize input offset drift. Charge injection in the analog switches and dc leakage currents at the sampling node are the primary sources of offset voltage drift in the converter. The dc input leakage current is essentially independent of the selected gain but charge injection effects will increase with increasing gain. As a result, the offset drift numbers will be slightly larger for higher gains. Gain drift within the converter depends primarily upon the temperature tracking of the internal capacitors. It is not affected by leakage currents.

Measurement errors due to offset drift or gain drift can be eliminated at any time by recalibrating the converter or by operating the part in the background calibration mode. Using the system calibration mode can also minimize offset and gain errors in the signal conditioning circuitry. Integral and differential linearity errors are not significantly affected by temperature changes.

POWER SUPPLIES AND GROUNDING

Since the analog inputs and reference input are differential, most of the voltages in the analog modulator are common-mode voltages. V_{BIAS} provides the return path for most of the analog currents flowing in the analog modulator. As a result, the V_{BIAS} input should be driven from a low impedance to minimize errors due to charging/discharging impedances on this line. When the internal reference is used as the reference source for the part, AGND is the ground return for this reference voltage.

The analog and digital supplies to the AD7710 are independent and separately pinned out to minimize coupling between the analog and digital sections of the device. The digital filter will provide rejection of broadband noise on the power supplies, except at integer multiples of the modulator sampling frequency. The digital supply (DV_{DD}) must never exceed the analog positive supply (AV_{DD}) by more than 0.3V. Power supply sequencing, therefore, is important. If separate analog and digital supplies are used, care must be taken to ensure that the analog supply is powered up first. If this cannot be ensured, or if DV_{DD} can exceed AV_{DD} at any other time, a Schottky diode should be placed between DV_{DD} and AV_{DD}.

DIGITAL INTERFACE

The AD7710's serial communications port provides a flexible arrangement to allow easy interfacing to industry standard microprocessors, microcontrollers and digital signal processors. A serial read to the AD7710 can access data from the output register, the control register or from the calibration registers. A serial write to the AD7710 can write data to the control register or the calibration registers.

Two different modes of operation are available, optimized for different types of interface where the AD7710 can act either as master in the system (it provides the serial clock) or as slave (an external serial clock can be provided to the AD7710). These two modes, labelled self clocking mode and external clocking mode, are discussed in detail in the following sections.

Self-Clocking Mode

The AD7710 is configured for its self-clocking mode by tying the MODE pin high. In this mode, the AD7710 provides the serial clock signal used for the transfer of data to and from the AD7710. This self-clocking mode can be used with processors which allow an external device to clock their serial port including most digital signal processors and microcontrollers such as the 68HC11 and 68HC05. It also allows easy interfacing to serial parallel conversion circuits in systems with parallel data communication, allowing interfacing to 74XX299 Universal Shift registers without any additional decoding. In the case of shift registers, the serial clock line should have a pull down resistor instead of the pull up resistor shown in Figure 8 and Figure 9.

Read Operation

Data can be read from either the output register, the control register or from the calibration registers. A0 determines whether the data read accesses data from the control register or from the output/calibration registers. This A0 signal must remain valid for the duration of the serial read operation. The function of the $\overline{DRDY}$ line is dependent only on the output update rate of the device and the reading of the output data register. $\overline{DRDY}$ only goes low when a new data word is available in the output data register. It is reset high when the last bit of data (either 16th bit or 24th bit) is read from the output register. If a new data word becomes available to the output register while data is being read from the output register, $\overline{DRDY}$ will not indicate this and the new data word will be lost to the user. $\overline{DRDY}$ is not affected by reading from the control register or the calibration registers.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Data can only be accessed from the output data register when $\overline{DRDY}$ is low. If $\overline{RFS}$ goes low while $\overline{DRDY}$ is high, the SCLK and SDATA lines will not become active until $\overline{DRDY}$ goes low. When $\overline{DRDY}$ goes low, the data word will then be output by the AD7710. If $\overline{RFS}$ goes low with $\overline{DRDY}$ high, no data transfer will take place until $\overline{DRDY}$ does go low. Provided $\overline{RFS}$ stays low for long enough, $\overline{RFS}$ can in most cases be brought low at any time with the AD7710 clocking the data into the microprocessor, microcontroller or shift register when its clock and data lines become active. $\overline{DRDY}$ does not have any effect on reading data from the control register or from the calibration registers.

Figures 8a and 8b show timing diagrams for reading from the AD7710 in the self-clocking mode. Figure 8a shows a situation where all the data is read from the AD7710 in one read operation. Figure 8b shows a situation where the data is read from the AD7710 over a number of read operations. Both read operations show a read from the AD7710's output data register. A read from the control register or calibration registers is similar but in these cases the $\overline{DRDY}$ line is not related to the read function. It can go low at any stage in the read cycle without affecting the read and its status should be ignored.

Figure 8a shows a read operation to the AD7710 where $\overline{RFS}$ remains low for the duration of the data word transmission. For the timing diagram shown, it is assumed that there is a pull up resistor on the SCLK output. With $\overline{DRDY}$ low, the $\overline{RFS}$ input is brought low. $\overline{RFS}$ going low enables the serial clock of the AD7710 and also places the MSB of the word on the serial data line. All subsequent data bits are clocked out on a high to low transition of the serial clock and are valid prior to the following rising edge of this clock. The final active falling edge of SCLK clocks out the LSB and this LSB is valid prior to the final active rising edge of SCLK. Coincident with the next falling edge of SCLK, $\overline{DRDY}$ is reset high. $\overline{DRDY}$ going high turns off the SCLK and the SDATA outputs. This means that the data hold time for the LSB is slightly shorter than for all other bits.

Figure 8b shows a timing diagram for a read operation where $\overline{RFS}$ returns high during the transmission of the word and returns low again to access the rest of the data word. As before, the waveform for SCLK assumes that there is a pull up resistor on this line. Timing parameters and functions are very similar to that outlined for Figure 8a, but Figure 8b has a number of additional times to show timing relationships when $\overline{RFS}$ returns high in the middle of transferring a word.

PRELIMINARY TECHNICAL DATA

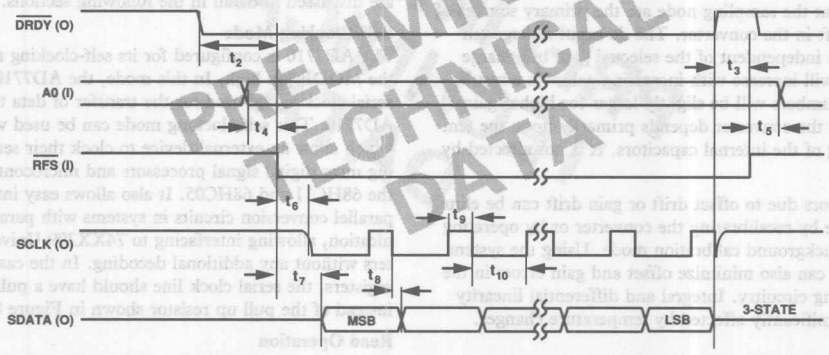

Figure 8a. Self-Clocking Mode, Output Data Read Operation

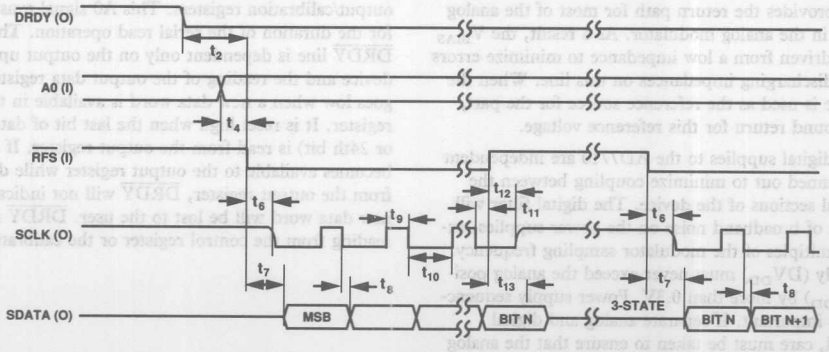

Figure 8b. Self-Clocking Mode, Output Data Read Operation ($\overline{RFS}$ Returns High During Read Operation)

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

$\overline{RFS}$ should return high during a low time of SCLK. On the rising edge of $\overline{RFS}$, the SCLK and SDATA outputs are turned off. $\overline{DRDY}$ remains low and will remain low until all bits of the data word are read from the AD7710, regardless of the number of times $\overline{RFS}$ changes state during the read operation. When $\overline{RFS}$ returns low again, it turns on the SCLK output and activates the SDATA output. The first bit placed on the SDATA line after $\overline{RFS}$ goes low is the same bit as appeared on the bus when $\overline{RFS}$ went high. When the entire word is transmitted, the $\overline{DRDY}$ line will go high turning off the SDATA and SCLK lines as per Figure 8a.

Write Operation

Data can be written to either the control register or calibration registers. In either case, the write operation is not affected by the $\overline{DRDY}$ line and the write operation does not have any effect on the status of $\overline{DRDY}$.

Figure 9a shows a write operation to the AD7710 with $\overline{TFS}$ remaining low for the duration of the write operation. A0 determines whether a write operation transfers data to the control register or to the calibration registers. This A0 signal must remain valid for the duration of the serial write operation. The falling edge of $\overline{TFS}$ enables the internally generated SCLK output. The serial data to be loaded to the AD7710 must be valid on the rising edge of this SCLK signal. Data is clocked into the AD7710 on the rising edge of the SCLK signal with the MSB transferred first. On the last active rising edge of SCLK, the LSB is loaded to the AD7710. Subsequent to the next falling edge of SCLK, the SCLK output is turned off. (The timing diagram of Figure 9a assumes a pull up resistor on the SCLK line.)

Figure 9b shows a timing diagram for a write operation to the AD7710 with $\overline{TFS}$ returning high during the write operation and returning low again to write the rest of the data word. Once again, the timing diagram of Figure 9b assumes a pull up resistor on the SCLK output. Timing parameters and functions are very similar to that outlined for Figure 9a but Figure 9b has a number of additional times to show timing relationships when $\overline{TFS}$ returns high in the middle of transferring a word.

The falling edge of $\overline{TFS}$ again initiates the SCLK output and data to be loaded to the AD7710 must be valid prior to the rising edge of this SCLK signal. The rising edge of $\overline{TFS}$ turns off the SCLK output. $\overline{TFS}$ should return high during the low time of SCLK. When $\overline{TFS}$ returns low again, it turns on the SCLK output. When all data bits have been written to the device, the SCLK output is turned off as per Figure 9a.

External Clocking Mode

The AD7710 is configured for its external clocking mode by tying the MODE pin low. In this mode, SCLK of the AD7710 is configured as an input and an external serial clock must be provided to this SCLK pin. This external clocking mode is designed for direct interface to systems which provide a serial clock output which is synchronized to the serial data output, including microcontrollers such as the 80C51, 87C51, 68HC11 and 68HC05 and most digital signal processors.

PRELIMINARY TECHNICAL DATA

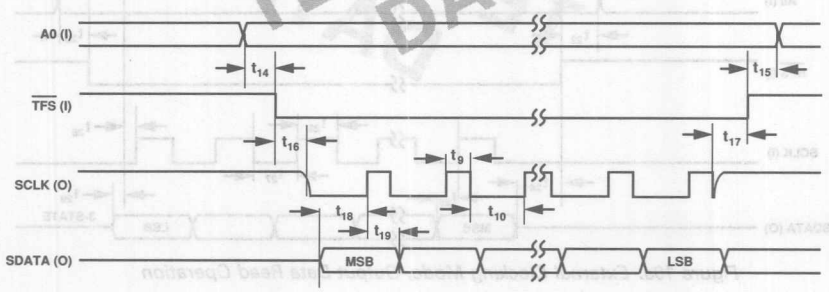

Figure 9a. Self-Clocking Mode, Control/Calibration Register Write Operation

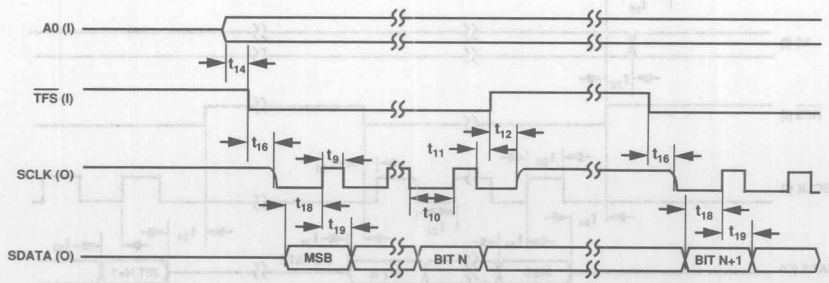

Figure 9b. Self-Clocking Mode, Control/Calibration Register Write Operation ($\overline{TFS}$ Returns High During Write Operation)

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

AD7710 in the external clocking mode. Figure 10a shows a situation where all the data is read from the AD7710 in one read operation. Figure 10b shows a situation where the data is read from the AD7710 over a number of read operations.

As with the self-clocking mode, data can be read from either the output register, the control register or from the calibration registers. A0 determines whether the data read accesses data from the control register or from the output/calibration registers. This A0 signal must remain valid for the duration of the serial read operation. The function of the $\overline{\text{DRDY}}$ line is dependent only on the output update rate of the device and the reading of the output data register. $\overline{\text{DRDY}}$ only goes low when a new data word is available in the output data register. It is reset high when the last bit of data (either 16th bit or 24th bit) is read from the output register. If a new data word becomes available to the output register while data is being read from the output register, $\overline{\text{DRDY}}$ will not indicate this and the new data word will be lost to the user. $\overline{\text{DRDY}}$ is not affected by reading from the control register or the calibration register.

Data can only be accessed from the output data register when $\overline{\text{DRDY}}$ is low. If $\overline{\text{RFS}}$ goes low while $\overline{\text{DRDY}}$ is high, the SDATA line will not become active until $\overline{\text{DRDY}}$ goes low. In this external clocking mode, an external clock is applied to the SCLK input. However, with $\overline{\text{DRDY}}$ high SDATA is not active and no data is transmitted. $\overline{\text{DRDY}}$ does not have any effect on reading data from the control register or from the calibration registers.

Figure 10a shows a read operation to the AD7710 where $\overline{\text{RFS}}$ remains low for the duration of the data word transmission. With $\overline{\text{DRDY}}$ low, the $\overline{\text{RFS}}$ input is brought low. The input SCLK signal should be low between read and write operations. $\overline{\text{RFS}}$ going low places the MSB of the word to be read on the serial data line. All subsequent data bits are clocked out on a high to low transition of the serial clock and are valid prior to the following rising edge of this clock. The penultimate falling edge of SCLK clocks out the LSB and the final falling edge resets the $\overline{\text{DRDY}}$ line high. This rising edge of $\overline{\text{DRDY}}$ turns off the serial data output.

Figure 10b shows a timing diagram for a read operation where $\overline{\text{RFS}}$ returns high during the transmission of the word and returns low again to access the rest of the data word. Timing parameters and functions are very similar to that outlined for Figure 10a but Figure 10b has a number of additional times to show timing relationships when $\overline{\text{RFS}}$ returns high in the middle of transferring a word.

PRELIMINARY TECHNICAL DATA

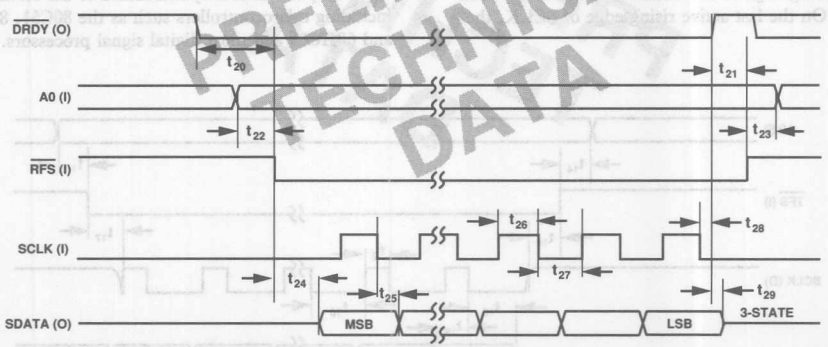

Figure 10a. External Clocking Mode, Output Data Read Operation

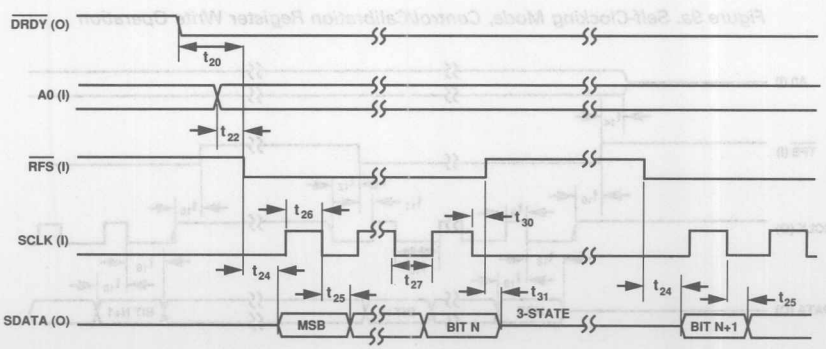

Figure 10b. External Clocking Mode, Output Data Read Operation ($\overline{\text{RFS}}$ Returns High During Read Operation)

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

$\overline{RFS}$ should return high during a low time of SCLK. On the rising edge of $\overline{RFS}$, the SDATA output is turned off. $\overline{DRDY}$ remains low and will remain low until all bits of the data word are read from the AD7710, regardless of the number of times $\overline{RFS}$ changes state during the read operation. When $\overline{RFS}$ returns low again, it activates the SDATA output and places the next bit of the data word on the SDATA output. When the entire word is transmitted, the $\overline{DRDY}$ line will go high turning off the SDATA output as per Figure 10a.

Write Operation

Data can be written to either the control register or calibration registers. In either case, the write operation is not affected by the $\overline{DRDY}$ line and the write operation does not have any effect on the status of $\overline{DRDY}$.

Figure 11a shows a write operation to the AD7710 with $\overline{TFS}$ remaining low for the duration of the write operation. A0 determines whether a write operation transfers data to the control register or to the calibration registers. This A0 signal must remain valid for the duration of the serial write operation. As before, the serial clock line should be low between read and write operations. The serial data to be loaded to the AD7710 must be valid on the high level of the externally applied SCLK signal. Data is clocked into the AD7710 on the high level of this SCLK signal with the MSB transferred first. On the last active rising edge of SCLK, the LSB is loaded to the AD7710.

Figure 11b shows a timing diagram for a write operation to the AD7710 with $\overline{TFS}$ returning high during the write operation and returning low again to write the rest of the data word. Timing parameters and functions are very similar to that outlined for Figure 11a but Figure 11b has a number of additional times to show timing relationships when $\overline{TFS}$ returns high in the middle of transferring a word.

Data to be loaded to the AD7710 must be valid prior to the rising edge of the SCLK signal. $\overline{TFS}$ should return high during the low time of SCLK. After $\overline{TFS}$ returns low again, the next bit of the data word to be loaded to the AD7710 is clocked in on next high level of the SCLK input. On the last active rising edge of the SCLK input, the LSB is loaded to the AD7710.

SIMPLIFYING THE INTERFACE

In some applications, the user may not require the facility of writing to the on-chip calibration registers. In this case, the serial interface to the AD7710 can be simplified by connecting the $\overline{TFS}$ line to the A0 input of the AD7710. This means that any write to the device will load data to the control register (since A0 is low while $\overline{TFS}$ is low) and any read to the device will access data from the output data register or from the calibration registers (since A0 is high while $\overline{RFS}$ is low). It should be noted that in this arrangement the user does not have the capability of reading from the control register.

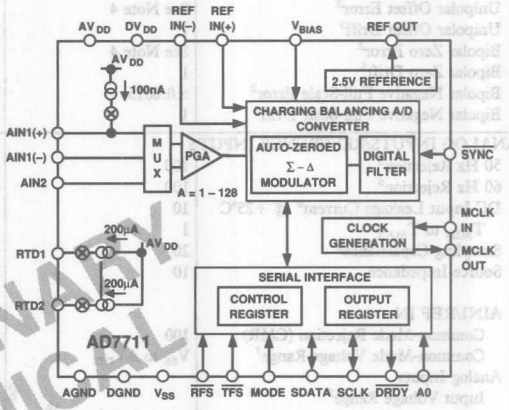
LC²MOS Signal Conditioning ADC with RTD Excitation Currents

AD7711*

FEATURES

Charge Balancing ADC
- **21 Bits No Missing Codes**
- **±0.0015% Nonlinearity**



Two-Channel Programmable Gain Front End
- **Gains from 1 to 128**
- **One Differential Input**
- **One Single-Ended Input**

Low-Pass Filter with Programmable Filter Cutoffs
Ability to Read/Write Calibration Coefficients
RTD Excitation Current Sources
Bidirectional Microcontroller Serial Interface
Internal/ External Reference Option
Single or Dual Supply Operation
Low Power (25 mW typ) with Power Down Mode (50 μW typ)

APPLICATIONS

RTD Transducers
Process Control
Smart Transmitters
Portable Industrial Instruments

FUNCTIONAL BLOCK DIAGRAM

PRELIMINARY TECHNICAL DATA

GENERAL DESCRIPTION

The AD7711 is a complete analog front end for low frequency measurement applications. The device accepts low level signals directly from a transducer and outputs a serial digital word. It employs a sigma-delta conversion technique to realize up to 21 bits of no missing codes performance. The input signal is applied to a proprietary programmable gain front end based around an analog modulator. The modulator output is processed by an on-chip digital filter. The first notch of this digital filter can be programmed via the on-chip control register allowing adjustment of the filter cutoff and settling time.

The part features one differential analog input and one single ended analog input as well as a differential reference input. Normally, one of the channels will be used as the main channel with the second channel used as an auxiliary input to periodically measure a second voltage. It can be operated from a single supply (by tying the V_{SS} pin to AGND) provided that the input signals on the analog inputs are more positive than −30 mV. By taking the V_{SS} pin negative, the part can convert signals down to $-V_{REF}$ on its inputs. The part provides two current sources that can be used to provide excitation in three-wire and four-wire RTD configurations. The AD7711 thus performs all signal conditioning and conversion for a single or dual channel system.

*Patent pending.

The AD7711 is ideal for use in smart, microcontroller based systems. Gain settings, signal polarity, input channel selection and RTD current control can be configured in software using the bidirectional serial port. The AD7711 contains self-calibration, system calibration and background calibration options and also allows the user to read and to write the on-chip calibration registers.

CMOS construction ensures low power dissipation and a software programmable power down mode reduces the standby power consumption to only 50 μW typical. The part is available in a 24-pin, 0.3 inch wide, plastic and hermetic dual-in-line package (DIP) as well as a 24-lead small outline (SOIC) package.

PRODUCT HIGHLIGHTS

1. The programmable gain front end allows the AD7711 to accept input signals directly from a strain gage or transducer, removing a considerable amount of signal conditioning. On-chip current sources provide excitation for three-wire and four-wire RTD configurations.
2. No Missing Codes ensures true, usable, 21-bit dynamic range coupled with excellent ±0.0015% accuracy. The effects of temperature drift are eliminated by on-chip self-calibration, which removes zero scale and full-scale errors.
3. The AD7711 is ideal for microcontroller or DSP processor applications with an on-chip control register which allows control over filter cutoff, input gain, channel selection, signal polarity, RTD current control and calibration modes.
4. The AD7711 allows the user to read and to write the on-chip calibration registers. This means that the microcontroller has much greater control over the calibration procedure.

Parameter	A, S Versions[1]	Units	Conditions/Comments
STATIC PERFORMANCE			
No Missing Codes	21	Bits min	Guaranteed by Design
Output Noise	See Tables I & II		Depends on Filter Cutoffs and Selected Gain
Integral Nonlinearity	±0.0015	% of FSR max	Filter Notches ≤ 60 Hz
Positive Full-Scale Error[2, 3]	See Note 4		Excluding Reference
Full-Scale Drift[5]	1	μV/°C max	Excluding Reference
Unipolar Offset Error[2]	See Note 4		
Unipolar Offset Drift[5]	1	μV/°C max	
Bipolar Zero Error[2]	See Note 4		
Bipolar Zero Drift[5]	1	μV/°C max	
Bipolar Negative Full-Scale Error[2]	±0.0015	% of FSR max	Excluding Reference; Typically ±0.0004%
Bipolar Negative Full-Scale Drift[5]	1	μV/°C max	Excluding Reference
ANALOG INPUTS/REFERENCE INPUTS			
50 Hz Rejection[6]	100	dB min	For Filter Notches of 10 Hz, 25 Hz, 50 Hz, $\pm 0.02 \times f_{NOTCH}$
60 Hz Rejection[6]	100	dB min	For Filter Notches of 10 Hz, 30 Hz, 60 Hz, $\pm 0.02 \times f_{NOTCH}$
DC Input Leakage Current[6] @ +25°C	10	pA max	
T_{MIN} to T_{MAX}	1	nA max	
Sampling Capacitance[6]	20	pF max	
Source Impedance	10	kΩ max	Maximum Allowable Output Impedance of Whatever Is Driving Either Analog Input
AIN1/REF IN			
Common-Mode Rejection (CMR)	100	dB min	At DC
Common-Mode Voltage Range[7]	V_{SS} to AV_{DD}	V min to V max	
Analog Inputs			
Input Voltage Range[8]			For Normal Operation; Depends On Gain Selected
	0 to $+V_{REF}$[9]	max	Unipolar Input Range (B/U Bit of Control Register = 0)
	$\pm V_{REF}$	max	Bipolar Input Range (B/U Bit Of Control Register = 1)
Input Sampling Rate, f_S	See Table III		
Reference Inputs			
REF IN(+) − REF IN(−) Voltage	+2.5 to +5	V min to V max	For Specified Performance
Input Sampling Rate, f_S	$f_{CLK\ IN}/512$		
REFERENCE OUTPUT			
Output Voltage	2.5	V nom	
Initial Tolerance	±1	% max	
Drift	25	ppm/°C typ	
Line Regulation (AV_{DD})	1	mV/V max	
Load Regulation	1	mV/mA max	Maximum Load Current 1 mA
External Current	1	mA max	
V_{BIAS} INPUT			
Input Voltage Range	$AV_{DD} - 0.85 \times V_{REF}$	V max	See V_{BIAS} Input Section
	$V_{SS} + 0.85 \times V_{REF}$	V min	
LOGIC INPUTS			
Input Current	±10	μA max	
All Inputs Except MCLK IN			
V_{INL}, Input Low Voltage	0.8	V max	
V_{INH}, Input High Voltage	2.0	V min	
MCLK IN Only			
V_{INL}, Input Low Voltage	0.8	V max	
V_{INH}, Input High Voltage	3.5	V min	

PRELIMINARY TECHNICAL DATA

Current	100	nA nom	
Initial Tolerance	±10	% typ	
Drift	100	ppm/°C typ	
SYSTEM CALIBRATION			
Positive Full-Scale Calibration Limit[11]	$(1.05 \times V_{REF})/GAIN$	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)
Negative Full-Scale Calibration Limit[11]	$-(1.05 \times V_{REF})/GAIN$	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)
Offset Calibration Limit[12]	$-(1.05 \times V_{REF})/GAIN$	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)
Input Span[12]	$0.8 \times V_{REF}/GAIN$	V min	GAIN Is the Selected PGA Gain (Between 1 and 128)
	$(2.1 \times V_{REF})/GAIN$	V max	GAIN Is the Selected PGA Gain (Between 1 and 128)
POWER REQUIREMENTS			
Power Supply Voltages			
$AV_{DD} - V_{SS}$ Voltage	+5 to +10	V nom	±10% for Specified Performance
DV_{DD} Voltage	+5	V nom	±10% for Specified Performance
Power Supply Currents			
AV_{DD} Current	3	mA max	
DV_{DD} Current	4	mA max	
V_{SS} Current	1.5	mA max	V_{SS} = −5 V
Power Supply Rejection[13]			Rejection w.r.t. AGND. Assumes V_{BIAS} Is Fixed
Positive Supply (AV_{DD})[14]	80	dB typ	
Negative Supply (V_{SS})	90	dB typ	
Power Dissipation			
Normal Mode	40	mW max	$AV_{DD} = DV_{DD}$ = +5 V, V_{SS} = 0 V; Typically 25 mW
Normal Mode	45	mW max	$AV_{DD} = DV_{DD}$ = +5 V, V_{SS} = −5 V; Typically 30 mW
Standby (Power-Down) Mode	100	μW max	$AV_{DD} = DV_{DD}$ = +5 V, V_{SS} = 0 V or −5 V; Typically 50 μW

PRELIMINARY TECHNICAL DATA

NOTES

[1]Temperature ranges are as follows: A Version, −40°C to +85°C; S Version −55°C to +125°C.

[2]Applies after calibration at the temperature of interest.

[3]Positive full-scale error applies to both unipolar and bipolar input ranges.

[4]These errors will be of the order of the output noise of the part, as shown in Table I.

[5]Recalibration at any temperature or use of the background calibration mode will remove these drift errors. These numbers are guaranteed by design and/or characterization.

[6]These numbers are guaranteed by design and/or characterization.

[7]This common-mode voltage range is allowed provided that the absolute value of the input voltage does not exceed AV_{DD} +30 mV and V_{SS} −30 mV.

[8]The analog inputs present a very high impedance dynamic load which varies with clock frequency and input sample rate. The maximum recommended source resistance is 10 kΩ.

[9]V_{REF} = REF IN(+) − REF IN(−).

[10]Sample tested at +25°C to ensure compliance.

[11]After calibration, if the analog input exceeds positive full scale then the converter will output all 1s. If the analog input is less than negative full scale, then the device will output all 0s.

[12]These calibration and span limits apply provided that the absolute voltage on the analog inputs does not exceed V_{DD} or does not go more negative than V_{SS} − 30 mV. The offset calibration limit applies to both the unipolar zero point and the bipolar zero point.

[13]Measured at dc and applies in the selected passband. PSRR at 50 Hz will exceed 120 dB with filter notches of 10 Hz, 25 Hz or 50 Hz. PSRR at 60 Hz will exceed 120 dB with filter notches of 10 Hz, 30 Hz or 60 Hz.

[14]This number can be improved (to 95 dB typ) by deriving the V_{BIAS} voltage (via Zener diode or reference) from the AV_{DD} supply.

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

TIMING CHARACTERISTICS[1, 2] (DV_{DD} = +5 V ± 10%; AV_{DD} = +5 V or +10 V ± 10%; V_{SS} = 0 V or −5 V ±10%; AGND = DGND = 0 V; f_{CLKIN} = 10 MHz; Input Logic 0 = 0 V, Logic 1 = DV_{DD}, unless otherwise stated.)

t_{35}	20	ns min	Data Valid to SCLK Setup Time
t_{36}	20	ns min	Data Valid to SCLK Hold Time

NOTES
[1]Sample tested at +25°C to ensure compliance. All input signals are specified with tr= tf= 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.
[2]See Figures 8 to 11.
[3]CLK IN Duty Cycle range is 20% to 80%. CLK IN must be supplied whenever the AD7711 is not in STANDBY mode. If no clock is present in this case, the device can draw higher current than specified and possibly become uncalibrated.
[4]The AD7711 is production tested with $f_{CLK\ IN}$ at 10 MHz. It is guaranteed by characterization to operate at 400 kHz.
[5]Specified using 10% and 90% points on waveform of interest.
[6]These numbers are measured with the load circuit of Figure 1 and defined as the time required for the output to cross 0.8 V or 2.4 V.
[7]These numbers are derived from the measured time taken by the data output to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove effects of charging or discharging the 100 pF capacitor. This means that the times quoted in the timing characteristics are the true bus relinquish times of the part and, as such, are independent of external bus loading capacitances.

PIN CONFIGURATION
DIP and SOIC

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

PIN FUNCTION DESCRIPTION

Pin	Mnemonic	Function
1	SCLK	Serial Clock. Logic Input/Output depending on the status of the MODE pin. When MODE is high, the device is in its self-clocking mode and the SCLK pin provides a serial clock output. This SCLK becomes active when $\overline{RFS}$ or $\overline{TFS}$ goes low and it goes high impedance when either $\overline{RFS}$ or $\overline{TFS}$ returns high or when the device has completed transmission of an output word. When MODE is low, the device is in its external clocking mode and the SCLK pin acts as an input. This input serial clock can be a continuous clock with all data transmitted in a continuous train of pulses. Alternatively, it can be a noncontinuous clock with the information being transmitted to the AD7711 in smaller batches of data.
2	MCLK IN	Master Clock signal for the device. This can be provided in the form of a crystal or external clock. A crystal can be tied across the MCLK IN and MCLK OUT pins. Alternatively, the MCLK IN pin can be driven with a CMOS-compatible clock and MCLK OUT left unconnected. The clock input frequency is nominally 10 MHz.
3	MCLK OUT	When the master clock for the device is a crystal, the crystal is connected between MCLK IN and MCLK OUT.
4	A0	Address Input. With this input low, reading and writing to the device is to the control register. With this input high, access is to either the data register or the calibration registers.
5	$\overline{SYNC}$	Logic Input which allows for synchronization of the digital filters when using a number of AD7711s. It resets the nodes of the digital filter.
6	MODE	Logic Input. When this pin is high, the device is in its self-clocking mode; with this pin low, the device is in its external clocking mode.
7	AIN1(+)	Analog Input Channel 1. Positive input of the programmable gain differential analog input. The AIN1(+) input is connected to an output current source which can be used to check that an external transducer has burnt out or gone open circuit. This output current source can be turned on/off via the control register.
8	AIN1(−)	Analog Input Channel 1. Negative input of the programmable gain differential analog input.
9	RTD1	Constant Current Output. A nominal 200 μA constant current is provided at this pin, and this can be used as the excitation current for RTDs. This current can be turned on or off via the control register
10	RTD2	Constant Current Output. A nominal 200 μA constant current is provided at this pin, and this can be used as the excitation current for RTDs. This current can be turned on or off via the control register. This second current can be used to eliminate lead resistance errors in three-wire RTD configurations.
11	V_{SS}	Analog Negative Supply, 0 V to −5 V. Tied to AGND for single supply operation. The input voltage on AIN1 or AIN2 should not go > 30 mV negative w.r.t. V_{SS} for correct operation of the device.
12	AV_{DD}	Analog Positive Supply Voltage, +5 V to +10 V.
13	V_{BIAS}	Input Bias Voltage. This input voltage should be set such that $V_{BIAS} + 0.85 \times V_{REF} < AV_{DD}$ and $V_{BIAS} - 0.85 \times V_{REF} > V_{SS}$ where V_{REF} is REF IN(+)− REF IN(−). Ideally, this should be tied halfway between AV_{DD} and V_{SS}. Thus, with AV_{DD} = +5 V and V_{SS} = 0 V, it can be tied to REF OUT; with AV_{DD} = +5 V and V_{SS} = −5 V, it can be tied to AGND, while with AV_{DD} = +10 V, it can be tied to +5 V or to REF OUT.
14	REF IN(−)	Reference Input. The REF IN(−) can lie anywhere between AV_{DD} and V_{SS} provided REF IN(+) is greater than REF IN(−).
15	REF IN(+)	Reference Input. The reference input is differential providing that REF IN(+) must be greater than REF IN(−). REF IN(+) can lie anywhere between AV_{DD} and V_{SS}.
16	REF OUT	Reference Output. The internal +2.5 V reference is provided at this pin. This is a single ended output which is referred to AGND. It is a buffered output is capable of providing 1 mA to an external load.
17	AIN2	Analog Input Channel 2. Single ended programmable gain analog input.
18	AGND	Ground reference point for analog circuitry.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Pin	Mnemonic	Function
19	$\overline{TFS}$	Transmit Frame Synchronization. Active low logic input used to write serial data to the device with serial data expected after the falling edge of this pulse. In the self-clocking mode, the serial clock becomes active after $\overline{TFS}$ goes low. During a write operation to the AD7711, the SDATA line should not return to high impedance until after $\overline{TFS}$ returns high.
20	$\overline{RFS}$	Receive Frame Synchronization. Active low logic input used to access serial data from the device. In the self-clocking mode, the SCLK and SDATA lines both become active after $\overline{RFS}$ goes low. In the external clocking mode, the SDATA line becomes active after $\overline{RFS}$ goes low.
21	$\overline{DRDY}$	Logic output. A falling edge indicates that a new output word is available for transmission. The $\overline{DRDY}$ pin will return high upon completion of transmission of a full output word. $\overline{DRDY}$ is also used to indicate when the AD7711 has completed its on-chip calibration sequence.
22	SDATA	Serial Data. Input /Output with serial data being written to either the control register or the calibration registers and serial data being accessed from the control register, calibration registers or the data register. During a read operation, serial data becomes active after $\overline{RFS}$ goes low. During a write operation, valid serial data is expected on the rising edges of SCLK when $\overline{TFS}$ is low.
23	DV_{DD}	Digital Supply Voltage, +5 V. DV_{DD} should never exceed AV_{DD} by more than 0.3 V. If DV_{DD} powers up before AV_{DD}, or if DV_{DD} can exceed AV_{DD} by more than 0.3 V at any other time, a Schottky diode should be placed between the two pins.
24	DGND	Ground reference point for digital circuitry.

TERMINOLOGY

INTEGRAL NONLINEARITY

This is the maximum deviation of any code from a straight line passing through the endpoints of the transfer function. The endpoints of the transfer function are zero scale (not to be confused with bipolar zero), a point 0.5 LSB below the first code transition (000 . . . 000 to 000 . . . 001) and full scale, a point 0.5 LSB above the last code transition (111 . . . 110 to 111 . . . 111). The error is expressed as a percentage of full scale.

POSITIVE FULL-SCALE ERROR

Positive full-scale error is the deviation of the last code transition (111 . . . 110 to 111 . . . 111) from the ideal input full-scale voltage. For AIN1(+), the ideal full-scale input voltage is (AIN1(−) + V_{REF}/GAIN −3/2 LSBs); for AIN2, the ideal full-scale input voltage is V_{REF}/GAIN −3/2 LSBs. It applies to both unipolar and bipolar analog input ranges.

UNIPOLAR OFFSET ERROR

Unipolar offset error is the deviation of the first code transition from the ideal input voltage. For AIN1(+), the ideal input voltage is (AIN1(−) + 0.5 LSB); for AIN2, the ideal input is 0.5 LSB when operating in the unipolar mode.

BIPOLAR ZERO ERROR

This is the deviation of the midscale transition (0111 . . . 111 to 1000 . . . 000) from the ideal input voltage. For AIN1(+), the ideal input voltage is (AIN1(−) −0.5 LSB); for AIN2, the ideal input is −0.5 LSB when operating in the bipolar mode.

BIPOLAR NEGATIVE FULL-SCALE ERROR

This is the deviation of the first code transition from the ideal input voltage. For AIN1(+), the ideal input voltage is (AIN1(−) −V_{REF}/GAIN + 0.5 LSB); for AIN2 the ideal input is −V_{REF}/GAIN + 0.5 LSB when operating in the bipolar mode.

POSITIVE FULL-SCALE OVERRANGE

Positive full-scale overrange is the amount of overhead available to handle input voltages on the AIN1(+) input greater than AIN1(−) +V_{REF}/GAIN or on the AIN2 input greater than +V_{REF}/GAIN (for example, noise peaks or excess voltages due to system gain errors in system calibration routines) without introducing errors due to overloading the analog modulator or to overflowing the digital filter.

NEGATIVE FULL-SCALE OVERRANGE

This is the amount of overhead available to handle voltages on AIN1(+) below AIN1(−) −V_{REF}/GAIN or on AIN2 below −V_{REF}/GAIN without overloading the analog modulator or overflowing the digital filter. Note that the analog input will accept negative voltage peaks on AIN1(+) even in the unipolar mode provided that AIN1(+) is greater than AIN1(−) and greater than V_{SS}−30 mV.

OFFSET CALIBRATION RANGE

In the system calibration modes, the AD7711 calibrates its offset with respect to the analog input. The offset calibration range specification defines the range of voltages that the AD7711 can accept and still calibrate offset accurately.

FULL-SCALE CALIBRATION RANGE

This is the range of voltages that the AD7711 can accept in the system calibration mode and still calibrate full scale correctly.

INPUT SPAN

In system calibration schemes, two voltages applied in sequence to the AD7711's analog input define the analog input range. The input span specification defines the minimum and maximum input voltages from zero to full scale that the AD7711 can accept and still calibrate gain accurately.

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

the contents of the control register.

Operating Mode

MD2	MD1	MD0	Operating Mode
0	0	0	Normal Mode. This is the normal mode of operation of the device whereby a read to the device with A0 high accesses data from the data register. This is the default condition of these bits after the internal power-on reset.
0	0	1	Activate Self-Calibration. This activates self-calibration on the channel selected by CH. This is a one-step calibration sequence, and when complete, the part returns to Normal Mode. The $\overline{DRDY}$ output indicates when this self-calibration is complete. For this calibration type, the zero scale calibration is done internally on AGND and the full-scale calibration is done internally on V_{REF}.
0	1	0	Activate System Calibration. This activates system calibration on the channel selected by CH. This is a two-step calibration sequence, with the zero scale calibration done first on the selected input channel and $\overline{DRDY}$ indicating when this zero scale calibration is complete. The part returns to Normal Mode at the end of this first step in the two-step sequence.
0	1	1	Activate System Calibration. This is the second step of the system calibration sequence with full-scale calibration being performed on the selected input channel. Once again, $\overline{DRDY}$ indicates when the full-scale calibration is complete. When this calibration is complete, the part returns to Normal Mode.
1	0	0	Activate System Offset Calibration. This activates system offset calibration on the channel selected by CH. This is a one step calibration sequence, and when complete, the part returns to Normal Mode with $\overline{DRDY}$ indicating when this system offset calibration is complete. For this calibration type, the zero scale calibration is done on the selected input channel and the full-scale calibration is done internally on V_{REF}.
1	0	1	Activate Background Calibration. This activates background calibration on the channel selected by CH. If the background calibration mode is on, then the AD7711 provides continuous self-calibration of the reference and AGND. This calibration takes place as part of the conversion sequence, extending the conversion time and reducing the word rate by a factor of six. Its major advantage is that the user does not have to worry about recalibrating the device when there is a change in the ambient temperature. In this mode, AGND and V_{REF}, as well as the analog input voltage, are continuously monitored and the calibration registers of the device are automatically updated, if necessary.
1	1	0	Read/Write Zero Scale Calibration Coefficients. A read to the device with A0 high accesses the contents of the zero scale calibration coefficients of the channel selected by CH. A write to the device with A0 high writes data to the zero scale calibration coefficients of the channel selected by CH. The word length for reading and writing these coefficients is 24 bits, regardless of the status of the WL bit of the control register.
1	1	1	Read/Write Full-Scale Calibration Coefficients. A read to the device with A0 high accesses the contents of the full-scale calibration coefficients of the channel selected by CH. A write to the device with A0 high writes data to the full-scale calibration coefficients of the channel selected by CH. The word length for reading and writing these coefficients is 24 bits, regardless of the status of the WL bit of the control register.

FILTER SECTION (FS11–FS0)

The on-chip digital filter provides a $Sinc^3$ (or $(Sinx/x)^3$ filter response. The 12 bits of data programmed into these bits determine the filter cutoff frequency, the position of the first notch of the filter and the data rate for the part. In association with the gain selection, it also determines the output noise (and hence the effective resolution) of the device.

The first notch of the filter occurs at a frequency determined by the relationship: filter first notch frequency = $(f_{CLK\ IN}/512)/code$ where *code* is the decimal equivalent of the code in bits FS0 to FS11 and is in the range 19 to 2,000. With the nominal $f_{CLK\ IN}$ of 10 MHz, this results in a first notch frequency range from 9.76 Hz to 1.028 kHz. To ensure correct operation of the AD7711, the value of the code loaded to these bits must be within this range. Failure to do this will result in unspecified operation of the device.

Changing the filter notch frequency, as well as the selected gain, impacts resolution. Tables I and II and Figure 2 show the effect of the filter notch frequency and gain on the effective resolution of the AD7711. The output data rate (or effective conversion time) for the device is equal to the frequency selected for the first notch of the filter. For example, if the first notch of the filter is selected at 50 Hz, then a new word is available at a 50 Hz rate or every 20 ms. If the first notch is at 1 kHz, a new word is available every 1 ms.

The settling time of the filter to a full-scale step input change is worst case 4× the data rate. For example, with the first filter notch at 50 Hz, the settling time of the filter to a full-scale step input change is 80 ms max. If the first notch is at 1 kHz, the settling time of the filter to a full-scale input step is 4 ms max.

The −3 dB frequency is determined by the programmed first notch frequency according to the relationship: filter −3 dB frequency = 0.262 × first notch frequency.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Table I shows the output rms noise for some typical notch and −3 dB frequencies. The numbers given are for the bipolar input ranges with a V_{REF} of +2.5 V. The numbers in Table I are guaranteed by a combination of testing, characterization and design. The output noise from the part comes from two sources: the quantization noise from the analog-to-digital conversion process and device noise. Device noise is independent of gain and is essentially flat across the frequency spectrum. Quantization noise is ratiometric to the input full-scale (and hence gain) and its frequency response is shaped by the modulator.

Looking at the table below, as the cutoff frequency increases, the output noise increases because more of the quantization noise of the part comes through to the output and, hence, the output noise increases with increasing −3 dB frequencies. For the lower notch settings, the output noise is dominated by the device noise and, hence, altering the gain has little effect on the output noise. At higher notch frequencies, the quantization noise dominates the output noise and, in this case, the output noise tends to decrease with increasing gain.

Since the output noise comes from two sources, the effective resolution of the device (i.e., the ratio of the output rms noise to the input full scale) does not remain constant with increasing gain or with increasing bandwidth. Table II shows the same table as Table I except that the output is now expressed in terms of effective resolution (the magnitude of the rms noise with respect to 2 × V_{REF}/GAIN, i.e., the input full scale). It is possible to do post filtering on the device to improve the output data rate for a given −3 dB frequency and also to further reduce the output noise (see Digital Filtering section).

Table I. Output Noise vs. Gain and First Notch Frequency

First Notch of Filter and O/P Data Rate[1]	Output RMS Noise (μV) −3 dB Frequency	Gain of 1	Gain of 2	Gain of 4	Gain of 8	Gain of 16	Gain of 32	Gain of 64	Gain of 128
10 Hz[2]	2.62 Hz	1.7	0.84	0.60	0.42	0.42	0.42	0.42	0.42
25Hz[2]	6.55 Hz	3.4	1.7	1.2	0.60	0.60	0.60	0.60	0.60
30 Hz[2]	7.86 Hz	3.4	2.4	1.2	0.84	0.84	0.60	0.60	0.60
50 Hz[2]	13.1 Hz	9.5	4.8	2.4	1.7	1.2	0.84	0.84	0.84
60 Hz[2]	15.72 Hz	13.5	6.7	3.4	1.7	1.2	1.2	0.84	0.84

500 Hz[3]	131 Hz	2.4×10^3	1.2×10^3	610	305	153	76	38	19
1 kHz[3]	262 Hz	13.8×10^3	6.9×10^3	3.4×10^3	1.7×10^3	863	432	216	108

NOTES
[1]The default condition (after the internal power-on reset) for the first notch of filter is 60 Hz.
[2]For these filter notch frequencies, the output rms noise is primarily independent of the value of the reference voltage. Therefore, increasing the reference voltage will give an increase in the effective resolution of the device (i.e., the ratio of the rms noise to the input full scale is increased since the output rms noise remains constant as the input full-scale increases).
[3]For these filter notch frequencies, the output rms noise is proportional to the value of the reference voltage.

Table II. Effective Resolution vs. Gain and First Notch Frequency

First Notch of Filter and O/P Data Rate	Effective Resolution[1] (Bits) −3 dB Frequency	Gain of 1	Gain of 2	Gain of 4	Gain of 8	Gain of 16	Gain of 32	Gain of 64	Gain of 128
10 Hz	2.62 Hz	21.5	21.5	21	20.5	19.5	18.5	17.5	16.5
25 Hz	6.55 Hz	20.5	20.5	20	20	19	18	17	16

50 Hz	13.1 Hz	19	19	19	18.5	18	17.5	16.5	15.5
60 Hz	15.72 Hz	18.5	18.5	18.5	18.5	18	17	16.5	15.5
100 Hz	26.2 Hz	16.5	16.5	16.5	16.5	16.5	16.5	15.5	15
250 Hz	65.5 Hz	13.5	13.5	13.5	13.5	13.5	13.5	13.5	13
500 Hz	131 Hz	11	11	11	11	11	11	11	11
1 kHz	262 Hz	8.5	8.5	8.5	8.5	8.5	8.5	8.5	8.5

NOTE
[1]Effective resolution is defined as the magnitude of the output rms noise to the input full scale (i.e., 2 × V_{REF}/GAIN). The above table applies for a V_{REF} of +2.5 V and resolution numbers are rounded to the nearest 0.5 LSB.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Figure 2 gives similar information to that outlined in Table I. In this plot, the output rms noise is shown for the full range of available cutoff frequencies rather than for some typical cutoff frequencies as in Tables I and II. The numbers given in this plot are typical values.

Figure 2. Plot of Output Noise vs. Gain and Notch Frequency

PRELIMINARY TECHNICAL DATA

CIRCUIT DESCRIPTION

The AD7711 is a sigma-delta A/D converter with on-chip digital filtering, intended for the measurement of wide dynamic range, low frequency signals such as those in RTD applications, industrial control or process control applications. It contains a sigma-delta (or charge balancing) ADC, a calibration microcontroller with on-chip static RAM, a clock oscillator, a digital filter and a bidirectional serial communications port.

The part contains two analog input channels, a programmable gain differential analog input and a programmable gain single ended input. The gain range is from 1 to 128 allowing the part to accept unipolar signals of between 0 to +20 mV and 0 V to +2.5 V or bipolar signals in the range from ±20 mV to ±2.5 V when the reference input voltage equals +2.5 V. The input signal to the selected analog input channel is continuously sampled at a rate determined by the frequency of the master clock, CLK IN, and the selected gain (see Table III). A charge balancing A/D converter (Sigma-Delta Modulator) converts the sampled signal into a digital pulse train whose duty cycle contains the digital information. The programmable gain function on the analog input is also incorporated in this sigma-delta modulator with the input sampling frequency being modified to give the higher gains. A sinc^3 digital low pass filter processes the output of the sigma-delta modulator and updates the output register at a rate determined by the first notch frequency of this filter. The output data can be read from the serial port randomly or periodically at any rate up to the output register update rate. The first notch of this digital filter (and hence its −3 dB frequency) can be programmed via an on-chip control register. The programmable range for this first notch frequency is from 9.76 Hz to 1.028 kHz, giving a programmable range for the −3 dB frequency of 2.58 Hz to 269 Hz.

The basic connection diagram for the part is shown in Figure 3. This shows the AD7711 in the external clocking mode with both the AV_{DD} and DV_{DD} pins of the AD7711 being driven from the analog +5 V supply. Some applications will have separate supplies for both AV_{DD} and DV_{DD} and, in some of these cases, the analog supply will exceed the +5 V digital supply (see Power Supplies and Grounding section).

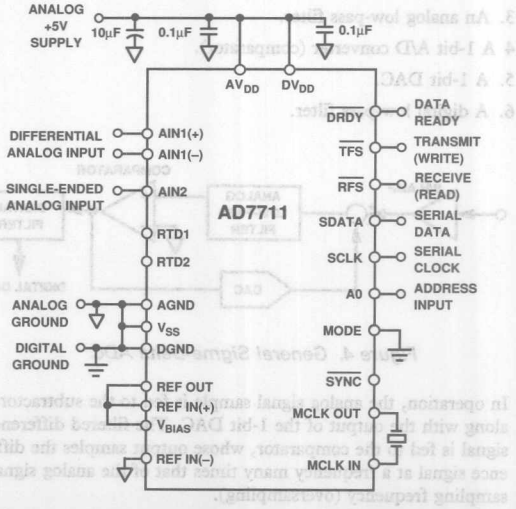

Figure 3. Basic Connection Diagram

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

register. The part can perform self-calibration using the on-chip calibration microcontroller and SRAM to store calibration parameters. Other system components may also be included in the calibration loop to remove offset and gain errors in the input channel using the system calibration mode. Another option is a background calibration mode where the part continuously performs self-calibration and updates the calibration coefficients. Once the part is in this mode, the user does not have to worry about issuing periodic calibration commands to the device or asking the device to recalibrate when there is a change in the ambient temperature or power supply voltage.

The AD7711 gives the user access to the on-chip calibration registers allowing the microprocessor to read the device's calibration coefficients and also to write its own calibration coefficients to the part. This gives the microprocessor much greater control over the AD7711's calibration procedure. It also means that the user can verify that the device has performed its calibration correctly by comparing the coefficients after calibration with prestored values in E^2PROM.

The AD7711 can be operated in single supply systems provided that the analog input voltage does not go more negative than 30 mV. For larger bipolar signals, a V_{SS} of −5 V is required by the part. For battery operation, the AD7711 also offers a software programmable standby mode that reduces idle power consumption to typically 50 μW.

THEORY OF OPERATION

The general block diagram of a sigma-delta ADC is shown in Figure 4. It contains the following elements:

1. A sample hold amplifier.
2. A differential amplifier or subtractor.
3. An analog low-pass filter.
4 A 1-bit A/D converter (comparator).
5. A 1-bit DAC.
6. A digital low-pass filter.

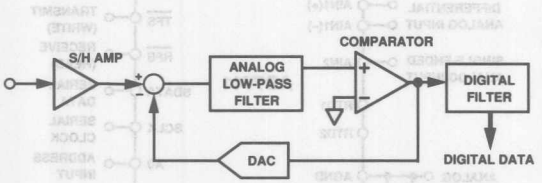

Figure 4. General Sigma-Delta ADC

In operation, the analog signal sample is fed to the subtractor, along with the output of the 1-bit DAC. The filtered difference signal is fed to the comparator, whose output samples the difference signal at a frequency many times that of the analog signal sampling frequency (oversampling).

$$SNR = (6.02 \times number\ of\ bits + 1.76)\ dB,$$

a 1-bit ADC or comparator yields an SNR of 7.78 dB.

The AD7711 samples the input signal at a frequency of 20 kHz or greater (see Table III). As a result, the quantization noise is spread over a much wider frequency than that of the band of interest. The noise in the band of interest is reduced still further by analog filtering in the modulator loop, which shapes the quantization noise spectrum to move most of the noise energy to frequencies outside the bandwidth of interest. The noise performance is thus improved from this 1-bit level to the performance outlined in Tables I and II and in Figure 2.

The output of the comparator provides the digital input for the 1–bit DAC, so that the system functions as a negative feedback loop that tries to minimize the difference signal. The digital data that represents the analog input voltage is contained in the duty cycle of the pulse train appearing at the output of the comparator. It can be retrieved as a parallel binary data word using a digital filter.

Sigma-delta ADCs are generally described by the order of the analog low pass filter. A simple example of a first order sigma-delta ADC is shown in Figure 5. This contains only a first order low pass filter or integrator. It also illustrates the derivation of the alternative name for these devices: Charge-Balancing ADCs.

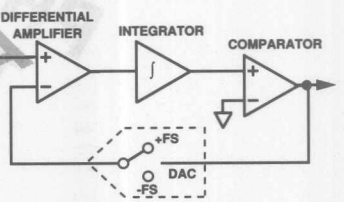

Figure 5. Basic Charge Balancing ADC

It consists of a differential amplifier (whose output is the difference between the analog input and the output of a 1-bit DAC), an integrator and a comparator. The term "charge balancing," comes from the fact that this system is a negative feedback loop that tries to keep the net charge on the integrator capacitor at zero, by balancing charge injected by the input voltage with charge injected by the 1-bit DAC. When the analog input is zero, the only contribution to the integrator output comes from the 1-bit DAC. For the net charge on the integrator capacitor to be zero, the DAC output must spend half its time at +FS and half its time at −FS. Assuming ideal components, the duty cycle of the comparator will be 50%.

When a positive analog input is applied, the output of the 1-bit DAC must spend a larger proportion of the time at +FS, so the duty cycle of the comparator increases. When a negative input voltage is applied, the duty cycle decreases.

The AD7711 uses a second-order sigma-delta modulator and a digital filter that provides a rolling average of the sampled output. After power-up, or if there is a step change in the input voltage, there is a settling time that must elapse before valid data is obtained.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Input Sample Rate

The modulator sample frequency for the device remains at $f_{CLK\ IN}/512$ (20 kHz @ $f_{CLK\ IN}$ = 10 MHz) regardless of the selected gain. However, gains greater than ×1 are achieved by a combination of multiple input samples per modulator cycle and a scaling of the ratio of reference capacitor to input capacitor. As a result of the multiple sampling, the input sample rate of the device varies with the selected gain (see Table III). The effective input impedance is $1/C \cdot f_S$ where C is the input sampling capacitance and f_S is the input sample rate.

Table III. Input Sampling Frequency vs. Gain

Gain	Input Sampling Frequency (f_S)
1	$f_{CLK\ IN}/512$ (20 kHz @ $f_{CLK\ IN}$ = 10 MHz)
2	$2 \times f_{CLK\ IN}/512$ (40 kHz @ $f_{CLK\ IN}$ = 10 MHz)
4	$4 \times f_{CLK\ IN}/512$ (80 kHz @ $f_{CLK\ IN}$ = 10 MHz)
8	$4 \times f_{CLK\ IN}/512$ (160 kHz @ $f_{CLK\ IN}$ = 10 MHz)
16	$4 \times f_{CLK\ IN}/512$ (160 kHz @ $f_{CLK\ IN}$ = 10 MHz)
32	$4 \times f_{CLK\ IN}/512$ (160 kHz @ $f_{CLK\ IN}$ = 10 MHz)
64	$4 \times f_{CLK\ IN}/512$ (160 kHz @ $f_{CLK\ IN}$ = 10 MHz)
128	$4 \times f_{CLK\ IN}/512$ (160 kHz @ $f_{CLK\ IN}$ = 10 MHz)

DIGITAL FILTERING

The AD7711's digital filter behaves like a similar analog filter, with a few minor differences.

First, since digital filtering occurs after the A-to-D conversion process, it can remove noise injected during the conversion process. Analog filtering cannot do this.

On the other hand, analog filtering can remove noise superimposed on the analog signal before it reaches the ADC. Digital filtering cannot do this and noise peaks riding on signals near full scale have the potential to saturate the analog modulator and digital filter, even though the average value of the signal is within limits. To alleviate this problem, the AD7711 has overrange headroom built into the sigma-delta modulator and digital filter which allows overrange excursions of 5% above the analog input range. If noise signals are larger than this, consideration should be given to analog input filtering, or to reducing the input channel voltage so that its full scale is half that of the analog input channel full scale. This will provide an overrange capability greater than 100% at the expense of reducing the dynamic range by 1 bit (50%).

Filter Characteristics

The cutoff frequency of the digital filter is determined by the value loaded to bits FS0 to FS11 in the control register. At the maximum clock frequency of 10 MHz, the minimum cutoff frequency of the filter is 2.58 Hz while the maximum programmable cutoff frequency is 269 Hz.

Figure 6 shows the filter frequency response for a cutoff frequency of 2.62 Hz which corresponds to a first filter notch frequency of 10 Hz. This is a $(\sin x/x)^3$ response (also called sinc^3) that provides >100 dB of 50 Hz and 60 Hz rejection. Programming a different cutoff frequency via FS0–FS11 does not alter the profile of the filter response; it changes the frequency of the notches as outlined in the Control Register section.

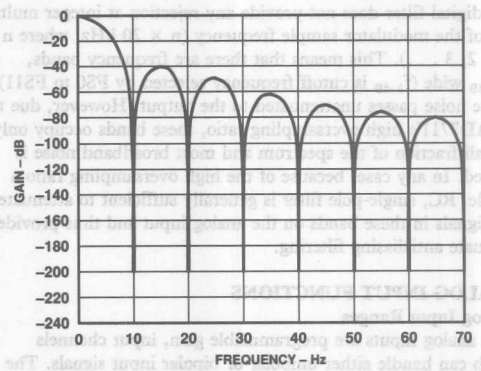

Figure 6. Frequency Response of AD7711 Filter

Since the AD7711 contains this on-chip, low pass filtering, there is a settling time associated with step function inputs, and data on the output will be invalid after a step change until the settling time has elapsed. The settling time depends upon the notch frequency chosen for the filter. The output data rate equates to this filter notch frequency and the settling time of the filter to a full-scale step input is 4 times the output data period. In applications using both input channels, the settling time of the filter must be allowed to elapse before data from the second channel is accessed.

Post Filtering

The on-chip modulator provides samples at a 20 kHz output rate. The on-chip digital filter decimates these samples to provide data at an output rate which corresponds to the programmed first notch frequency of the filter. Since the output data rate exceeds the Nyquist criterion, the output rate for a given bandwidth will satisfy most application requirements. However, there may be some applications which require a higher data rate for a given bandwidth and noise performance. Applications which need this higher data rate will require some post filtering following the digital filter of the AD7711.

For example, if the required bandwidth is 7.86 Hz but the required update rate is 100 Hz, the data can be taken from the AD7711 at the 100 Hz rate giving a −3 dB bandwidth of 26.2 Hz. Post filtering can be applied to this to reduce the bandwidth and output noise, to the 7.86 Hz bandwidth level, while maintaining an output rate of 100 Hz.

Post filtering can also be used to reduce the output noise from the device for bandwidths below 2.62 Hz. At a gain of 128, the output rms noise is 420 nV. This is essentially device noise or white noise, and since the input is chopped, the noise has a flat frequency response. By reducing the bandwidth below 2.62 Hz, the noise in the resultant passband can be reduced. A reduction in bandwidth by a factor of 2 results in a $\sqrt{2}$ reduction in the output rms noise. This additional filtering will result in a longer settling time.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Antialias Considerations

The digital filter does not provide any rejection at integer multiples of the modulator sample frequency (n × 20 kHz, where n = 1, 2, 3 . . .). This means that there are frequency bands, $\pm f_{3\ dB}$ wide ($f_{3\ dB}$ is cutoff frequency selected by FS0 to FS11) where noise passes unattenuated to the output. However, due to the AD7711's high oversampling ratio, these bands occupy only a small fraction of the spectrum and most broadband noise is filtered. In any case, because of the high oversampling ratio a simple, RC, single-pole filter is generally sufficient to attenuate the signals in these bands on the analog input and thus provide adequate antialiasing filtering.

ANALOG INPUT FUNCTIONS

Analog Input Ranges

Both analog inputs are programmable gain, input channels which can handle either unipolar or bipolar input signals. The AIN1 channel is a differential input channel having a common-mode range from V_{SS} to AV_{DD}, provided that the absolute value of the analog input voltage lies between V_{SS} −30 mV and AV_{DD} +30 mV. The AIN2 input channel is a single-ended input that is referred to AGND.

The input sample rate for the part varies as per Table III and the input sampling capacitance is 15 pF typical. The effective input impedance is $1/C \cdot f_S$. This results in a maximum allowable source impedance of whatever is driving the analog input of 10 kΩ to ensure correct charging of the sampling capacitor.

The dc input leakage current is 10 pA maximum at +25°C. This results in a dc offset voltage developed across the source impedance. However, this dc offset effect can be compensated for by a combination of the differential input capability of the part and its system calibration mode.

Burn-Out Current

The AIN1(+) input of the AD7711 contains a 100 nA current source which can be turned on/off via the control register. This current source can be used in checking that a transducer has not burnt out or gone open circuit before attempting to take measurements on that channel. If the current is turned on and is allowed flow into the transducer and a measurement of the input voltage on the AIN1 input is taken, it can indicate that the transducer is malfunctioning. For normal operation, this burn-out current is turned off by writing a 0 to the BO bit in the control register.

RTD Excitation Currents

The AD7711 also contains two matched 200 μA constant current sources which are provided at the RTD1 and RTD2 pins of the device. These currents can be turned on/off via the control register. Writing a 1 to the RO bit of the control register enables these excitation currents.

For four-wire RTD applications, one of these excitation currents is used to provide the excitation current for the RTD, the second current source can be left unconnected. For three-wire RTD configurations, the second on-chip current source can be used to eliminate errors due to voltage drops across lead resistances.

The temperature coefficient of the RTD current sources is typically 35 ppm/°C with a typical matching between the temperature coefficients of both current sources of 5 ppm/°C. For applications where the absolute value of the temperature coefficient is too large, the following schemes can be used to remove the drift error.

The conversion result from the AD7711 is ratiometric to the V_{REF} voltage. Therefore, if the V_{REF} voltage varies with the RTD temperature coefficient, the temperature drift from the current source will be removed. For four-wire RTD applications, the reference voltage can be made ratiometric to RTD current source by using the second current with a low t.c. resistor to generate the reference voltage for the part. In this case, if a 12.5 kΩ resistor is used, the 200 μA current source generates +2.5 V across the resistor. This +2.5 V can be applied to the REF IN(+) input of the AD7711 and with the REF IN(−) input at ground it will supply a V_{REF} of 2.5 V for the part. For three-wire RTD configurations, the reference voltage for the part is generated by placing a low t.c. resistor (12.5 kΩ for 2.5 V reference) in series with one of the constant current sources. The RTD current sources can be driven to within 2 V of AV_{DD}. The reference input of the AD7711 is differential so the REF IN(+) and REF IN(−) of the AD7711 are driven from either side of the resistor. Both schemes ensure that the reference voltage for the part tracks the RTD current sources over temperature and, thereby, removes the temperature drift error.

Bipolar/Unipolar Inputs

The two analog inputs on the AD7711 can accept either unipolar or bipolar input voltage ranges. Bipolar or unipolar options are chosen by programming the B/U bit of the control register. This programs both channels for either unipolar or bipolar operation. Programming the part for either unipolar or bipolar operation does not change any of the input signal conditioning; it simply changes the data output coding.

The AIN1 input channel is differential and, as a result, the voltage to which the unipolar and bipolar signals are referenced is the voltage on the AIN1(−) input. For example, if AIN1(−) is +1.25 V and the AD7711 is configured for unipolar operation with a gain of 1 and a V_{REF} of +2.5 V, the input voltage range on the AIN1(+) input is +1.25 V to +3.75 V. If AIN1(−) is +1.25 V and the AD7711 is configured for bipolar mode with a gain of 1 and a V_{REF} of +2.5 V, the analog input range on the AIN1(+) input is −1.25 V to +3.75 V. For the AIN2 input, the input signals are referenced to AGND.

REFERENCE INPUT/OUTPUT

The AD7711 contains a temperature compensated +2.5 V reference which has an initial tolerance of ±25 mV. This reference voltage is provided at the REF OUT pin and it can be used as the reference voltage for the part by connecting the REF OUT pin to the REF IN(+) pin. This REF OUT pin is a single ended output, referenced to AGND, which is capable of providing up to 1 mA to an external load. In applications where REF OUT is connected directly to REF IN(+), REF IN(−) should be tied to AGND to provide the nominal +2.5 V reference for the AD7711.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

The reference inputs of the AD7711, REF IN(+) and REF IN(−), provide a differential reference input capability. The common-mode range for these differential inputs is from V_{SS} to AV_{DD}. The nominal differential voltage, V_{REF} (REF IN(+) −REF IN(−)), is +2.5 V for specified operation but the reference voltage can go to +5 V with no degradation in performance provided that the absolute value of REF IN(+) and REF IN(−) does not exceed its AV_{DD} and V_{SS} limits. REF IN(+) must always be greater than REF IN(−) for correct operation of the AD7711.

Both reference inputs provide a high impedance, dynamic load similar to the analog inputs. The maximum dc input leakage current is 10 pA (±1 μA over temperature) and source resistances will result in gain errors on the part. The reference inputs are switched capacitor inputs with the input capacitance dependent upon the selected gain. For gains of 1 to 8 the input capacitance is 20 pF; for a gain of 16 it is 10 pF; for a gain of 32 it is 5 pF; for a gain of 64 it is 2.5 pF; and for a gain of 128 it is 1.25 pF.

The digital filter of the AD7711 removes noise from the reference input just as it does with the analog input, and the same limitations apply regarding lack of noise rejection at integer multiples of the sampling frequency. The output noise performance outlined in Tables I and II assumes a clean reference. If the reference noise in the bandwidth of interest is excessive, it can degrade the performance of the AD7711. Figure 7 shows the noise performance of the AD7711's onboard reference.

PRELIMINARY TECHNICAL DATA

V_{BIAS} Input

The V_{BIAS} input determines at what voltage the internal analog circuitry is biased. It essentially provides the return path for analog currents flowing in the modulator and, as such, it should be driven from a low impedance point to minimize errors.

For maximum internal headroom, the V_{BIAS} voltage should be set halfway between AV_{DD} and V_{SS}. The difference between AV_{DD} and (V_{BIAS} + 0.85 × V_{REF}) determines the amount of headroom the circuit has at the upper end, while the difference between V_{SS} and (V_{BIAS} −0.85 × V_{REF}) determines the amount of headroom the circuit has at the lower end. Care should be taken in choosing a V_{BIAS} voltage to ensure that V_{BIAS} ±0.85 × V_{REF} does not exceed the AV_{DD} and V_{SS} limits. For example, with AV_{DD} = +4.75 V, V_{SS} = 0 V and V_{REF} = +2.5 V, the allowable range for the V_{BIAS} voltage is +2.125 V to +2.625 V. With AV_{DD} = +9.5 V, V_{SS} = 0 V and V_{REF} = +5 V, the range for V_{BIAS} is +4.25 V to +5.25 V. With AV_{DD} = +4.75 V, V_{SS} = −4.75 V and V_{REF} = +2.5 V, the V_{BIAS} range is −2.625 V to +2.625 V.

USING THE AD7711

SYSTEM DESIGN CONSIDERATIONS

The AD7711 operates differently from successive approximation ADCs or integrating ADCs. Since it samples the signal continuously, like a tracking ADC, there is no need for a start convert command. The output register is updated at a rate determined by the first notch of the filter and the output can be read at any time, either synchronously or asynchronously.

Clocking

The AD7711 requires a master clock input, which may be an external TTL/CMOS compatible clock signal applied to the MCLK IN pin with the MCLK OUT pin left unconnected. Alternatively, a crystal of the correct frequency can be connected between MCLK IN and MCLK OUT, in which case the clock circuit will function as a crystal controlled oscillator. For lower clock frequencies, a ceramic resonator may be used instead of the crystal. For these lower frequency oscillators, external capacitors may be required on either the ceramic resonator or on the crystal.

The input sampling frequency, the modulator sampling frequency, the −3 dB frequency, output update rate and calibration time are all directly related to the master clock frequency, $f_{CLK\ IN}$. Reducing the master clock frequency by a factor of 2 will halve the above frequencies and update rate and will double the calibration time.

The current drawn from the DV_{DD} power supply is also directly related to $f_{CLK\ IN}$. Reducing $f_{CLK\ IN}$ by a factor of 2 will halve the DV_{DD} current but will not affect the current drawn from the AV_{DD} power supply.

System Synchronization

If multiple AD7711s are operated from a common master clock, they can be synchronized to update their output registers simultaneously. A falling edge on the $\overline{SYNC}$ input resets the filter and places the AD7711 into a consistent, known state. A common signal to the AD7711s' $\overline{SYNC}$ inputs will synchronize their operation. This would normally be done after each AD7711 has performed its own calibration or has had calibration coefficients loaded to it.

ACCURACY

Sigma-Delta ADCs, like VFCs and other integrating ADCs, do not contain any source of nonmonotonicity and inherently offer no missing codes performance. The AD7711 achieves excellent linearity by the use of high quality, on-chip silicon dioxide capacitors, which have a very low capacitance/voltage coefficient. The device also achieves low input drift through the use of chopper stabilized techniques in its input stage. To ensure excellent performance over time and temperature, the AD7711 uses digital calibration techniques that minimize offset and gain error.

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

from the device. A calibration routine should be initiated on the device whenever there is a change in the ambient operating temperature or supply voltage. It should also be initiated if there is a change in the selected channel, gain, filter notch or bipolar/unipolar input range. However, if the AD7711 is in its background calibration mode, the above changes are all automatically taken care of (after the settling time of the filter has been allowed for).

The AD7711 offers self-calibration, system calibration and background calibration facilities. For calibration to occur on the selected channel, the on-chip microcontroller must record the modulator output for two different input conditions. These are "zero-scale" and "full-scale" points. With these readings, the microcontroller can calculate the gain slope for the input to output transfer function of the converter. Internally, the part works with a resolution of 33 bits to determine its conversion result of either 16 bits or 24 bits.

Self-Calibration

In the self-calibration mode with a unipolar input range, the zero scale point used in determining the calibration coefficients is AGND and the full-scale point is V_{REF}. The zero scale coefficient is determined by converting an internal AGND node. The full-scale coefficient is determined from the span between this AGND conversion and a conversion on an internal V_{REF} node. The self-calibration mode is invoked by writing the appropriate values (0, 0, 1) to the MD2, MD1 and MD0 bits of the control register. In this calibration mode, the AGND node is switched in to the modulator first and a conversion is performed; the V_{REF} node is then switched in and another conversion is performed. When the calibration sequence is complete, the calibration coefficients updated and the filter resettled to the analog input voltage, the $\overline{DRDY}$ output goes low.

For bipolar input ranges in the self-calibrating mode, the sequence is very similar to that just outlined. In this case, the two points which the AD7711 calibrates are midscale (bipolar zero) and positive full scale.

System Calibration

System calibration allows the AD7711 to compensate for system gain and offset errors as well as its own internal errors. System calibration performs the same slope factor calculations as self-calibration but uses voltage values presented by the system to the AIN inputs for the zero and full-scale points. System calibration is a two-step process. The zero scale point must be presented to the converter first. It must be applied to the converter before the calibration step is initiated and must remain stable until the step is complete. System calibration is initiated by writing the appropriate values (0, 1, 0) to the MD2, MD1 and MD0 bits of the i.e., control register. The $\overline{DRDY}$ output from the device will signal when the step is complete by going low. After the zero-scale point is calibrated, the full-scale point is applied and the second step of the calibration process is initiated by again writing the appropriate values (0, 1, 1) to MD2, MD1 and MD0. Again the full-scale voltage must be set up before the calibration is initiated and it must remain stable throughout the calibration step. $\overline{DRDY}$ goes low at the end of this second step to indicate that the system calibration is complete. In the unipolar mode of the transfer function, it is performed between midscale and positive full scale.

This two-step system calibration mode offers another feature. After the sequence has been completed, additional offset calibrations can be performed by themselves to adjust the zero reference point to a new system zero reference value. This is achieved by performing the first step of the system calibration sequence (by writing 0, 1, 0 to MD2, MD1, MD0). This will adjust the zero scale or offset point but will not change the slope factor from what was set during a full system calibration sequence.

System Offset Calibration

System offset calibration is a variation of both the system calibration and self-calibration. In this case, the zero scale point for the system is presented to the AIN input of the converter. System offset calibration is initiated by writing 1, 0, 0 to MD2, MD1, MD0. The system zero scale coefficient is determined by converting the voltage applied to the AIN input, while the full-scale coefficient is determined from the span between this AIN conversion and a conversion on an internal V_{REF} node. The zero scale point should be applied to the AIN input for the duration of the calibration sequence. This is a one-step calibration sequence with $\overline{DRDY}$ going low when the sequence is completed. In the unipolar mode, the system offset calibration is performed between the two end points of the transfer function; in the bipolar mode, it is performed between midscale and positive full scale.

Background Calibration

The AD7711 also offers a background calibration mode where the part interleaves its calibration procedure with its normal conversion sequence. In the background calibration mode, the same nodes are used as the calibration points as are used in the self-calibration mode (i.e., AGND and V_{REF}). The background calibration mode is invoked by writing 1, 0, 1 to MD2, MD1, MD0 of the control register. When invoked, the background calibration mode reduces the output data rate of the AD7711 by a factor of six. Its advantage is that the part is continually performing calibration and automatically updating its calibration coefficients. As a result, the effects of temperature drift, supply sensitivity and time drift on zero and full scale errors are automatically removed. When the background calibration mode is turned on, the part will remain in this mode until bits MD2, MD1 and MD0 of the control register are changed.

Table IV summarizes the calibration modes and the calibration points associated with them.

Span and Offset Limits

Whenever a system calibration mode is used, there are limits on the amount of offset and span that can be accommodated. The range of input span in both the unipolar and bipolar modes has a minimum value of $0.8 \times V_{REF}/GAIN$ and a maximum value of $2.1 \times V_{REF}/GAIN$.

The amount of offset that can be accommodated depends on whether the unipolar or bipolar mode is being used. In unipolar mode, the system calibration modes can handle a maximum offset of $0.25 \times V_{REF}/GAIN$ and a minimum offset of $-(1.05 \times V_{REF}/GAIN)$. This offset range is limited by the requirement

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Table IV. Calibration Truth Table

Cal Type	MD2, MD1, MD0	Zero Scale Cal	Full-Scale Cal	Sequence
Self-Cal	0, 0, 1	AGND	V_{REF}	One Step
System Cal	0, 1, 0	AIN		Two Step
System Cal	0, 1, 1		AIN	Two Step
System Offset Cal	1, 0, 0	AIN	V_{REF}	One Step
Background Cal	1, 0, 1	AGND	V_{REF}	One Step

that the positive full-scale calibration limit is $\leq 1.05 \times V_{REF}$/GAIN. Thus, the maximum offset ($0.25 \times V_{REF}$/GAIN) plus the minimum span ($0.8 \times V_{REF}$/GAIN) cannot exceed $1.05 \times V_{REF}$/GAIN.

In the bipolar mode, the system offset calibration range is restricted to $\pm 0.65 \times V_{REF}$/GAIN. The span range of the converter in bipolar mode is equidistant around the voltage used for the zero scale point. Therefore, the maximum offset $\pm(0.65 \times V_{REF}$/GAIN) plus half the minimum span $\pm(0.4 \times V_{REF}$/GAIN) must be less than $\pm(1.05 \times V_{REF}$/GAIN). If the span is set to $2 \times V_{REF}$/GAIN, the input offset cannot move more than $\pm(0.05 \times V_{REF}$/GAIN) before the endpoints of the transfer function exceed the input overrange limits $\pm(1.05 \times V_{REF}$/GAIN).

POWER-UP AND CALIBRATION

On power-up, the AD7711 performs an internal reset which sets the contents of the control register to a known state. However, to ensure correct calibration for the device, a calibration routine should be performed after power-up.

The power dissipation and temperature drift of the AD7711 are low and no warm up time is required before the initial calibration is performed. However, if an external reference is being used, this reference must have stabilized before calibration is initiated.

Drift Considerations

The AD7711 uses chopper stabilization techniques to minimize input offset drift. Charge injection in the analog switches and dc leakage currents at the sampling node are the primary sources of offset voltage drift in the converter. The dc input leakage current is essentially independent of the selected gain but charge injection effects will increase with increasing gain. As a result, the offset drift numbers will be slightly larger for higher gains. Gain drift within the converter depends primarily upon the temperature tracking of the internal capacitors. It is not affected by leakage currents.

Measurement errors due to offset drift or gain drift can be eliminated at any time by recalibrating the converter or by operating the part in the background calibration mode. Using the system calibration mode can also minimize offset and gain errors in the signal conditioning circuitry. Integral and differential linearity errors are not significantly affected by temperature changes.

POWER SUPPLIES AND GROUNDING

Since the analog inputs and reference input are differential, most of the voltages in the analog modulator are common-mode voltages. V_{BIAS} provides the return path for most of the analog currents flowing in the analog modulator. As a result, the V_{BIAS} input should be driven from a low impedance to minimize errors due to charging/discharging impedances on this line. When the internal reference is used as the reference source for the part, AGND is the ground return for this reference voltage.

The analog and digital supplies to the AD7711 are independent and separately pinned out to minimize coupling between the analog and digital sections of the device. The digital filter will provide rejection of broadband noise on the power supplies, except at integer multiples of the modulator sampling frequency. The digital supply (DV_{DD}) must never exceed the analog positive supply (AV_{DD}) by more than 0.3 V. Power supply sequencing, therefore, is important. If separate analog and digital supplies are used, care must be taken to ensure that the analog supply is powered up first. If this cannot be ensured, or if DV_{DD} can exceed AV_{DD} at any other time, a Schottky diode should be placed between DV_{DD} and AV_{DD}.

DIGITAL INTERFACE

The AD7711's serial communications port provides a flexible arrangement to allow easy interfacing to industry standard microprocessors, microcontrollers and digital signal processors. A serial read to the AD7711 can access data from the output register, the control register or from the calibration registers. A serial write to the AD7711 can write data to the control register or the calibration registers.

Two different modes of operation are available, optimized for different types of interface where the AD7711 can act either as master in the system (it provides the serial clock) or as slave (an external serial clock can be provided to the AD7711). These two modes, labelled self-clocking mode and external clocking mode, are discussed in detail in the following sections.

Self-Clocking Mode

The AD7711 is configured for its self-clocking mode by tying the MODE pin high. In this mode, the AD7711 provides the serial clock signal used for the transfer of data to and from the AD7711. This self-clocking mode can be used with processors that allow an external device to clock their serial port, including most digital signal processors and microcontrollers such as the 68HC11 and 68HC05. It also allows easy interfacing to serial parallel conversion circuits in systems with parallel data communication, allowing interfacing to 74XX299 Universal Shift registers without any additional decoding. In the case of shift registers, the serial clock line should have a pull-down resistor instead of the pull-up resistor shown in Figure 8 and Figure 9.

Read Operation

Data can be read from either the output register, the control register or the calibration registers. A0 determines whether the data read accesses data from the control register or from the output/calibration registers. This A0 signal must remain valid for

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

the duration of the serial read operation. The function of the $\overline{DRDY}$ line is dependent only on the output update rate of the device and the reading of the output data register. $\overline{DRDY}$ only goes low when a new data word is available in the output data register. It is reset high when the last bit of data (either 16th bit or 24th bit) is read from the output register. If a new data word becomes available to the output register while data is being read from the output register, $\overline{DRDY}$ will not indicate this and the new data word will be lost to the user. $\overline{DRDY}$ is not affected by reading from the control register or the calibration registers.

Data can only be accessed from the output data register when $\overline{DRDY}$ is low. If $\overline{RFS}$ goes low while $\overline{DRDY}$ is high, the SCLK and SDATA lines will not become active until $\overline{DRDY}$ goes low. When $\overline{DRDY}$ goes low, the data word will then be output by the AD7711. If $\overline{RFS}$ goes low with $\overline{DRDY}$ high, no data transfer will take place until $\overline{DRDY}$ does go low. Provided $\overline{RFS}$ stays low for long enough, $\overline{RFS}$ can, in most cases, be brought low at any time with the AD7711 clocking the data into the microprocessor, microcontroller or shift register when its clock and data lines become active. $\overline{DRDY}$ does not have any effect on reading data from the control register or from the calibration registers.

Figures 8a and 8b show timing diagrams for reading from the AD7711 in the Self-Clocking mode. Figure 8a shows a situation where all the data is read from the AD7711 in one read operation. Figure 8b shows a situation where the data is read from the AD7711 over a number of read operations. Both read operations show a read from the AD7711's output data register. A read from the control register or calibration registers is similar but in these cases the $\overline{DRDY}$ line is not related to the read function. It can go low at any stage in the read cycle without affecting the read and its status should be ignored.

Figure 8a shows a read operation to the AD7711 where $\overline{RFS}$ remains low for the duration of the data word transmission. For the timing diagram shown, it is assumed that there is a pull up resistor on the SCLK output. With $\overline{DRDY}$ low, the $\overline{RFS}$ input is brought low. $\overline{RFS}$ going low enables the serial clock of the AD7711 and also places the MSB of the word on the serial data line. All subsequent data bits are clocked out on a high to low transition of the serial clock and are valid prior to the following rising edge of this clock. The final active falling edge of SCLK clocks out the LSB and this LSB is valid prior to the final active rising edge of SCLK. Coincident with the next falling edge of

PRELIMINARY TECHNICAL DATA

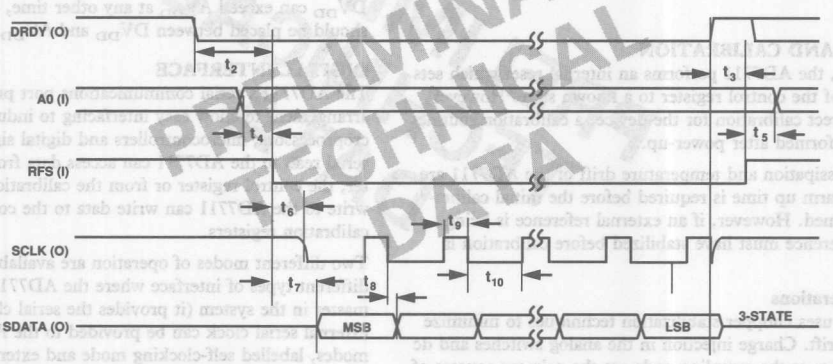

Figure 8a. Self-Clocking Mode, Output Data Read Operation

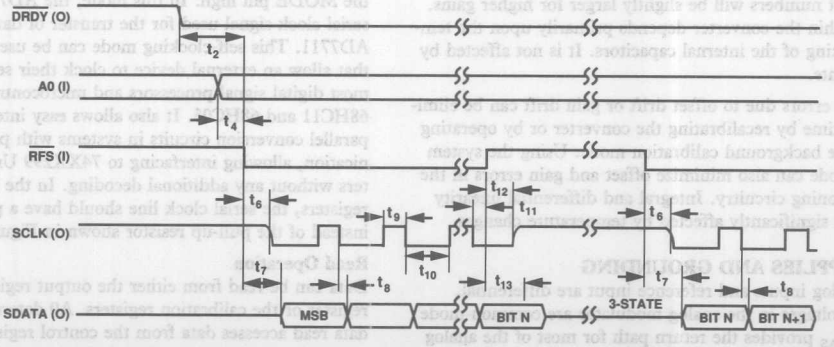

Figure 8b. Self-Clocking Mode, Output Data Read Operation ($\overline{RFS}$ Returns High During Read Operation)

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

SCLK, $\overline{DRDY}$ is reset high. $\overline{DRDY}$ going high turns off the SCLK and the SDATA outputs. This means that the data hold time for the LSB is slightly shorter than for all other bits.

Figure 8b shows a timing diagram for a read operation where $\overline{RFS}$ returns high during the transmission of the word and returns low again to access the rest of the data word. As before, the waveform for SCLK assumes that there is a pull up resistor on this line. Timing parameters and functions are very similar to that outlined for Figure 8a but Figure 8b has a number of additional times to show timing relationships when $\overline{RFS}$ returns high in the middle of transferring a word.

$\overline{RFS}$ should return high during a low time of SCLK. On the rising edge of $\overline{RFS}$, the SCLK and SDATA outputs are turned off. $\overline{DRDY}$ remains low and will remain low until all bits of the data word are read from the AD7711, regardless of the number of times $\overline{RFS}$ changes state during the read operation. When $\overline{RFS}$ returns low again, it turns on the SCLK output and activates the SDATA output. The first bit placed on the SDATA line after $\overline{RFS}$ goes low is the same bit as appeared on the bus when $\overline{RFS}$ went high. When the entire word is transmitted, the $\overline{DRDY}$ line will go high turning off the SDATA and SCLK lines as per Figure 8a.

Write Operation

Data can be written to either the control register or calibration registers. In either case, the write operation is not affected by the $\overline{DRDY}$ line and the write operation does not have any effect on the status of $\overline{DRDY}$.

Figure 9a shows a write operation to the AD7711 with $\overline{TFS}$ remaining low for the duration of the write operation. A0 determines whether a write operation transfers data to the control register or to the calibration registers. This A0 signal must remain valid for the duration of the serial write operation. The falling edge of $\overline{TFS}$ enables the internally generated SCLK output. The serial data to be loaded to the AD7711 must be valid on the rising edge of this SCLK signal. Data is clocked into the AD7711 on the rising edge of the SCLK signal with the MSB transferred first. On the last active rising edge of SCLK, the LSB is loaded to the AD7711. Subsequent to the next falling edge of SCLK, the SCLK output is turned off. (The timing diagram of Figure 9a assumes a pull up resistor on the SCLK line.)

Figure 9b shows a timing diagram for a write operation to the AD7711 with $\overline{TFS}$ returning high during the write operation and returning low again to write the rest of the data word. Once again, the timing diagram of Figure 9b assumes a pull up resistor on the SCLK output. Timing parameters and functions are very similar to that outlined for Figure 9a, but Figure 9b has a number of additional times to show timing relationships when $\overline{TFS}$ returns high in the middle of transferring a word.

The falling edge of $\overline{TFS}$ again initiates the SCLK output and data to be loaded to the AD7711 must be valid prior to the rising edge of this SCLK signal. The rising edge of $\overline{TFS}$ turns off the SCLK output. $\overline{TFS}$ should return high during the low time of SCLK . When $\overline{TFS}$ returns low again, it turns on the SCLK output. When all data bits have been written to the device, the SCLK output is turned off as per Figure 9a.

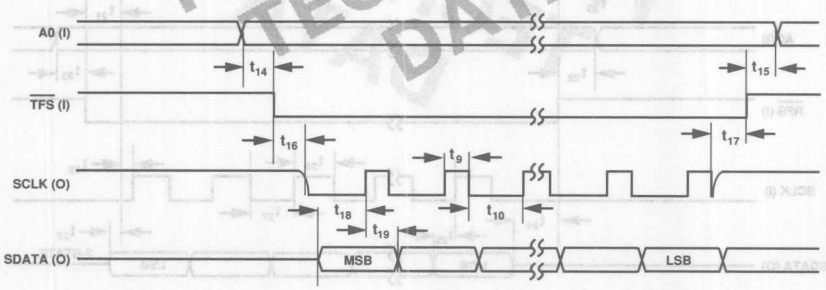

Figure 9a. Self-Clocking Mode, Control/Calibration Register Write Operation

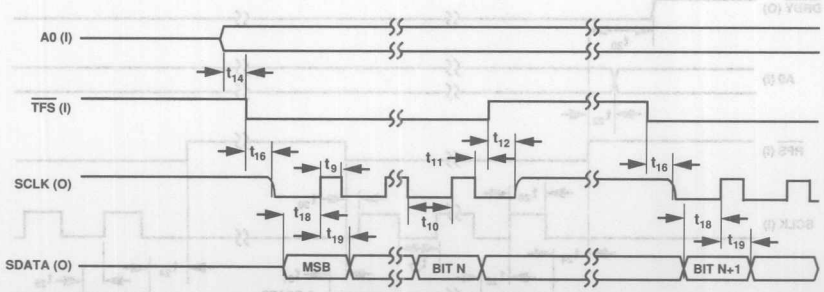

Figure 9b. Self-Clocking Mode, Control/Calibration Register Write Operation ($\overline{TFS}$ Returns High During Write Operation)

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

External Clocking Mode

The AD7711 is configured for its external clocking mode by tying the MODE pin low. In this mode, SCLK of the AD7711 is configured as an input and an external serial clock must be provided to this SCLK pin. This external clocking mode is designed for direct interface to systems which provide a serial clock output that is synchronized to the serial data output, including microcontrollers such as the 80C51, 87C51, 68HC11 and 68HC05 and most digital signal processors.

Read Operation

Figures 10a and 10b show timing diagrams for reading from the AD7711 in the external clocking mode. Figure 10a shows a situation where all the data is read from the AD7711 in one read operation. Figure 10b shows a situation where the data is read from the AD7711 over a number of read operations.

As with the self-clocking mode, data can be read from either the output register, the control register or the calibration registers. A0 determines whether the data read accesses data from the control register or from the output/calibration registers. This A0 signal must remain valid for the duration of the serial read operation. The function of the $\overline{DRDY}$ line is dependent only on the output update rate of the device and the reading of the output data register. $\overline{DRDY}$ only goes low when a new data word is available in the output data register. It is reset high when the last bit of data (either 16th bit or 24th bit) is read from the output register. If a new data word becomes available to the output register while data is being read from the output register, $\overline{DRDY}$ will not indicate this and the new data word will be lost to the user. $\overline{DRDY}$ is not affected by reading from the control register or the calibration register.

Data can only be accessed from the output data register when $\overline{DRDY}$ is low. If $\overline{RFS}$ goes low while $\overline{DRDY}$ is high, the SDATA line will not become active until $\overline{DRDY}$ goes low. In this external clocking mode, an external clock is applied to the SCLK input. The receiving device (microprocessor or microcontroller) expects to see valid data on edges of this SCLK signal. However, with $\overline{DRDY}$ high SDATA is not active and no data is transmitted. $\overline{DRDY}$ does not have any effect on reading data from the control register or from the calibration registers.

Figure 10a shows a read operation to the AD7711 where $\overline{RFS}$ remains low for the duration of the data word transmission. With $\overline{DRDY}$ low, the $\overline{RFS}$ input is brought low. The input SCLK signal should be low between read and write operations. $\overline{RFS}$ going low places the MSB of the word to be read on the serial data line. All subsequent data bits are clocked out on a high to low transition of the serial clock and are valid prior to the following rising edge of this clock. The penultimate falling edge of SCLK clocks out the LSB and the final falling edge resets the $\overline{DRDY}$ line high. This rising edge of $\overline{DRDY}$ turns off the serial data output.

Figure 10b shows a timing diagram for a read operation where $\overline{RFS}$ returns high during the transmission of the word and re-

turns low again to access the rest of the data word. Timing parameters and functions are very similar to that outlined for Figure 10a but Figure 10b has a number of additional times to show timing relationships when $\overline{RFS}$ returns high in the middle of transferring a word.

$\overline{RFS}$ should return high during a low time of SCLK. On the rising edge of $\overline{RFS}$, the SDATA output is turned off. $\overline{DRDY}$ remains low and will remain low until all bits of the data word are read from the AD7711, regardless of the number of times $\overline{RFS}$ changes state during the read operation. When $\overline{RFS}$ returns low again, it activates the SDATA output and places the next bit of the data word on the SDATA output. When the entire word is transmitted, the $\overline{DRDY}$ line will go high turning off the SDATA output as per Figure 10a.

Write Operation

Data can be written to either the control register or calibration registers. In either case, the write operation is not affected by the $\overline{DRDY}$ line and the write operation does not have any effect on the status of $\overline{DRDY}$.

Figure 11a shows a write operation to the AD7711 with $\overline{TFS}$ remaining low for the duration of the write operation. A0 determines whether a write operation transfers data to the control register or to the calibration registers. This A0 signal must remain valid for the duration of the serial write operation. As before, the serial clock line should be low between read and write operations. The serial data to be loaded to the AD7711 must be valid on the high level of the externally applied SCLK signal. Data is clocked into the AD7711 on the high level of this SCLK signal with the MSB transferred first. On the last active rising edge of SCLK, the LSB is loaded to the AD7711.

Figure 11b shows a timing diagram for a write operation to the AD7711 with $\overline{TFS}$ returning high during the write operation and returning low again to write the rest of the data word. Timing parameters and functions are very similar to that outlined for Figure 11a, but Figure 11b has a number of additional times to show timing relationships when $\overline{TFS}$ returns high in the middle of transferring a word.

Data to be loaded to the AD7711 must be valid prior to the rising edge of the SCLK signal. $\overline{TFS}$ should return high during the low time of SCLK . After $\overline{TFS}$ returns low again, the next bit of the data word to be loaded to the AD7711 is clocked in on next high level of the SCLK input. On the last active rising edge of the SCLK input, the LSB is loaded to the AD7711 as per Figure 11a.

SIMPLIFYING THE INTERFACE

In some applications, the user may not require the facility of writing to the on-chip calibration registers. In this case, the serial interface to the AD7711 can be simplified by connecting the $\overline{TFS}$ line to the A0 input of the AD7711. This means that any write to the device will load data to the control register (since A0 is low while $\overline{TFS}$ is low) and any read to the device will access data from the output data register or from the calibration registers (since A0 is high while $\overline{RFS}$ is low). It should be noted that in this arrangement the user does not have the capability of reading from the control register.

PRELIMINARY TECHNICAL DATA

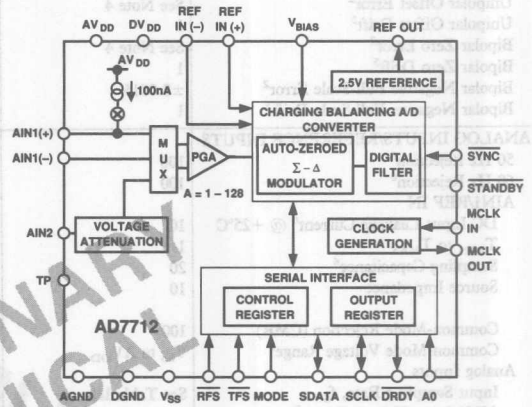
AD7712*



FEATURES

Charge Balancing ADC
21 Bits No Missing Codes
±0.0015% Nonlinearity
High Level and Low Level Analog Input Channels
Programmable Gain for Both Inputs
Gains from 1 to 128
Differential Input for Low Level Channel
Low-Pass Filter with Programmable Filter Cutoffs
Ability to Read/Write Calibration Coefficients
Bidirectional Microcontroller Serial Interface
Internal/ External Reference Option
Single or Dual Supply Operation
Low Power (25 mW typ) with Power-Down Mode (50 μW typ)

APPLICATIONS

Process Control
Smart Transmitters
Portable Industrial Instruments

FUNCTIONAL BLOCK DIAGRAM

PRELIMINARY TECHNICAL DATA

GENERAL DESCRIPTION

The AD7712 is a complete analog front end for low frequency measurement applications. The device has two analog input channels and accepts either low level signals directly from a transducer or high level ($\pm 4 \times V_{REF}$) signals and outputs a serial digital word. It employs a sigma-delta conversion technique to realize up to 21 bits of no missing codes performance. The low level input signal is applied to a proprietary programmable gain front end based around an analog modulator. The high-level analog input is attenuated before being applied to the same modulator. The modulator output is processed by an on-chip digital filter. The first notch of this digital filter can be programmed via the on-chip control register allowing adjustment of the filter cutoff and settling time.

Normally, one of the channels will be used as the main channel with the second channel used as an auxiliary input to periodically measure a second voltage. The part can be operated from a single supply (by tying the V_{SS} pin to AGND) provided that the input signals on the low level analog input are more positive than −30 mV. By taking the V_{SS} pin negative, the part can convert signals down to $-V_{REF}$ on this low level input. This low-level input, as well as the reference input, features differential input capability.

The AD7712 is ideal for use in smart, microcontroller based systems. Input channel selection, gain settings and signal polarity can be configured in software using the bidirectional serial port. The AD7712 also contains self-calibration, system calibration and background calibration options and also allows the user to read and to write the on-chip calibration registers.

CMOS construction ensures low power dissipation and a software programmable power-down mode reduces the standby power consumption to only 50 μW typical. The part is available in a 24-pin, 0.3 inch wide, plastic and hermetic dual-in-line package (DIP) as well as a 24-lead small outline (SOIC) package.

PRODUCT HIGHLIGHTS

1. The low level analog input channel allows the AD7712 to accept input signals directly from a strain gage or transducer, removing a considerable amount of signal conditioning. To maximize the flexibility of the part, the high level analog input accepts signals of $\pm 4 \times V_{REF}$/GAIN.
2. The AD7712 is ideal for microcontroller or DSP processor applications with an on-chip control register that allows control over filter cutoff level, input gain, channel selection, signal polarity and calibration modes.
3. The AD7712 allows the user to read and to write the on-chip calibration registers. This means that the microcontroller has much greater control over the calibration procedure.
4. No Missing Codes ensures true, usable, 21-bit dynamic range coupled with excellent ±0.0015% accuracy. The effects of temperature drift are eliminated by on-chip self-calibration, which removes zero scale and full-scale errors.

POWER REQUIREMENTS			
Power Supply Voltages			
AV_{DD} − V_{SS} Voltage	+5 to +10	V nom	±10% for Specified Performance
DV_{DD} Voltage	+5	V nom	±10% for Specified Performance
Power Supply Currents			
AV_{DD} Current	3	mA max	
DV_{DD} Current	4	mA max	
V_{SS} Current	1.5	mA max	V_{SS} = −5 V
Power Supply Rejection[14]			Rejection w.r.t. AGND. Assumes V_{BIAS} Is Fixed.
Positive Supply (AV_{DD})[15]	80	dB typ	
Negative Supply (V_{SS})	90	dB typ	
Power Dissipation			
Normal Mode	40	mW max	AV_{DD} = DV_{DD} = +5 V, V_{SS} = 0 V; Typically 25 mW
Normal Mode	45	mW max	AV_{DD} = DV_{DD} = +5 V, V_{SS} = −5 V; Typically 30 mW
Standby (Power-Down) Mode	100	μW max	AV_{DD} = DV_{DD} = +5 V, V_{SS} = 0 V or −5 V; Typically 50 μW

NOTES

[1]Temperature ranges are as follows: A Version, −40°C to +85°C; S Version −55°C to +125°C.

[2]Applies after calibration at the temperature of interest.

[3]Positive full-scale error applies to both unipolar and bipolar input ranges.

[4]These errors will be of the order of the output noise of the part, as shown in Table I.

[5]Recalibration at any temperature or use of the background calibration mode will remove these drift errors. These numbers are guaranteed by design and/or characterization.

[6]These numbers are guaranteed by design and/or characterization.

[7]This common-mode voltage range is allowed provided that the absolute value of the input voltage does not exceed AV_{DD} +30 mV and V_{SS} −30 mV.

[8]The AIN1 analog input presents a very high impedance dynamic load which varies with clock frequency and input sample rate. The maximum recommended source resistance is 10 kΩ.

[9]V_{REF} = REF IN(+) − REF IN(−).

[10]Sample tested at +25°C to ensure compliance.

[11]After calibration, if the analog input exceeds positive full scale, the converter will output all 1s. If the analog input is less than negative full scale, then the device will output all 0s.

[12]These calibration and span limits apply provided that the absolute voltage on the analog inputs does not exceed V_{DD} or does not go more negative than V_{SS} − 30 mV.

[13]The offset calibration limit applies to both the unipolar zero point and the bipolar zero point.

[14]Measured at dc and applies in the selected passband. PSRR at 50 Hz will exceed 120 dB with filter notches of 10 Hz, 25 Hz or 50 Hz. PSRR at 60 Hz will exceed 120 dB with filter notches of 10 Hz, 30 Hz or 60 Hz.

[15]This number can be improved (to 95 dB typ) by deriving the V_{BIAS} voltage (via Zener diode or reference) from the AV_{DD} supply.

Specifications subject to change without notice.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

AV_{DD} to V_{SS}	−0.3 V to +12 V
AV_{DD} to AGND	−0.3 V to +12 V
AV_{DD} to DGND	−0.3 V to +12 V
DV_{DD} to AGND	−0.3 V to +6 V
DV_{DD} to DGND	−0.3 V to +6 V
V_{SS} to AGND	+0.3 V to −6 V
V_{SS} to DGND	+0.3 V to −6 V
AGND to DGND	−0.3 V to AV_{DD}+0.3 V
Analog Input Voltage to AGND	V_{SS}−0.3 V to AV_{DD}+0.3 V
Reference Input Voltage to AGND	V_{SS}−0.3 V to AV_{DD}+0.3 V
REF OUT to AGND	−0.3 V to AV_{DD}

Operating Temperature Range	
Commercial (A Version)	−40°C to +85°C
Extended (S Version)	−55°C to +125°C
Storage Temperature Range	−65°C to +150°C
Lead Temperature (Soldering, 10 secs)	+300°C
Power Dissipation (Any Package) to +75°C	450 mW

*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

TIMING CHARACTERISTICS[1, 2] (DV_{DD} = +5 V ± 10%; AV_{DD} = +5 V or +10 V ± 10%; V_{SS} = 0 V or −5 V ±10%; AGND = DGND = 0 V; f_{CLKIN} = 10 MHz; Input Logic 0 = 0 V, Logic 1 = DV_{DD}, unless otherwise stated.)

t_{36}	20	ns min	Data Valid to SCLK Hold Time

NOTES

[1]Sample tested at +25°C to ensure compliance. All input signals are specified with tr= tf= 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

[2]See Figures 9 to 12.

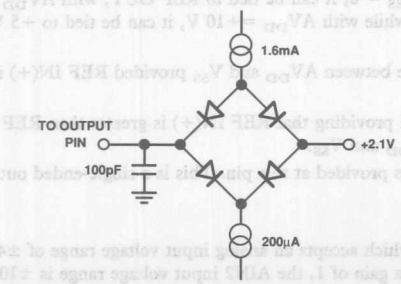
[3]CLK IN duty cycle range is 20% to 80%. CLK IN must be supplied whenever the AD7712 is not in STANDBY mode. If no clock is present in this case, the device can draw higher current than specified and possibly become uncalibrated.

[4]The AD7712 is production tested with $f_{CLK\ IN}$ at 10 MHz. It is guaranteed by characterization to operate at 400 kHz.

[5]Specified using 10% and 90% points on waveform of interest.

[6]These numbers are measured with the load circuit of Figure 1 and defined as the time required for the output to cross 0.8 V or 2.4 V.

[7]These numbers are derived from the measured time taken by the data output to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove effects of charging or discharging the 100 pF capacitor. This means that the times quoted in the timing characteristics are the true bus relinquish times of the part and, as such, are independent of external bus loading capacitances.



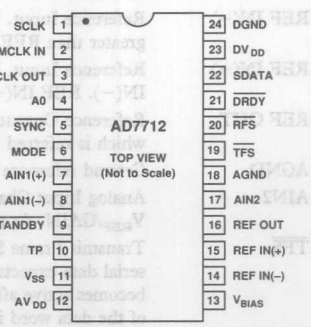


Figure 1. Load Circuit for Access Time and Bus Relinquish Time

PIN CONFIGURATION
DIP and SOIC

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

PIN FUNCTION DESCRIPTION

Pin	Mnemonic	Function
1	SCLK	Serial Clock. Logic Input/Output depending on the status of the MODE pin. When MODE is high, the device is in its self-clocking mode and the SCLK pin provides a serial clock output. This SCLK becomes active when $\overline{RFS}$ or $\overline{TFS}$ goes low and it goes high impedance when either $\overline{RFS}$ or $\overline{TFS}$ returns high or when the device has completed transmission of an output word. When MODE is low, the device is in its external clocking mode and the SCLK pin acts as an input. This input serial clock can be a continuous clock with all data transmitted in a continuous train of pulses. Alternatively, it can be a noncontinuous clock with the information being transmitted to the AD7712 in smaller batches of data.
2	MCLK IN	Master Clock signal for the device. This can be provided in the form of a crystal or external clock. A crystal can be tied across the MCLK IN and MCLK OUT pins. Alternatively, the MCLK IN pin can be driven with a CMOS-compatible clock and MCLK OUT left unconnected. The clock input frequency is nominally 10 MHz.
3	MCLK OUT	When the master clock for the device is a crystal, the crystal is connected between MCLK IN and MCLK OUT.
4	A0	Address Input. With this input low, reading and writing to the device is to the control register. With this input high, access is to either the data register or the calibration registers.
5	$\overline{SYNC}$	Logic Input which allows for synchronization of the digital filters when using a number of AD7712s. It resets the nodes of the digital filter.
6	MODE	Logic Input. When this pin is high, the device is in its self-clocking mode; with this pin low, the device is in its external clocking mode.
7	AIN1(+)	Analog Input Channel 1. Positive input of the programmable gain differential analog input. The AIN1(+) input is connected to an output current source which can be used to check that an external transducer has burnt out or gone open circuit. This output current source can be turned on/off via the control register.
8	AIN1(−)	Analog Input Channel 1. Negative input of the programmable gain differential analog input.
9	$\overline{STANDBY}$	Logic Input. Taking this pin low shuts down the internal analog and digital circuitry, reducing power consumption to less than 50 μW.
10	TP	Test Pin. Used when testing the device. Do not connect anything to this pin.
11	V_{SS}	Analog Negative Supply, 0 to −5 V. Tied to AGND for single supply operation. The input voltage on AIN1 should not go > 30 mV negative w.r.t. V_{SS} for correct operation of the device.
12	AV_{DD}	Analog Positive Supply Voltage, +5 V to +10 V.
13	V_{BIAS}	Input Bias Voltage. This input voltage should be set such that $V_{BIAS} + V_{REF} < V_{DD}$ and $V_{BIAS} - V_{REF} > V_{SS}$ where V_{REF} is REF IN(+) − REF IN(−). Ideally, this should be tied halfway between AV_{DD} and V_{SS}. Thus, with AV_{DD} = +5 V and V_{SS} = 0, it can be tied to REF OUT; with AV_{DD} = +5 V and V_{SS} = −5 V, it can be tied to AGND, while with AV_{DD} = +10 V, it can be tied to +5 V or to REF OUT.
14	REF IN(−)	Reference Input. The REF IN(−) can lie anywhere between AV_{DD} and V_{SS} provided REF IN(+) is greater than REF IN(−).
15	REF IN(+)	Reference Input. The reference input is differential providing that REF IN(+) is greater than REF IN(−). REF IN(+) can lie anywhere between AV_{DD} and V_{SS}.
16	REF OUT	Reference Output. The internal +2.5 V reference is provided at this pin. This is a single-ended output which is referred to AGND.
17	AGND	Ground reference point for analog circuitry.
18	AIN2	Analog Input Channel 2. High-level analog input which accepts an analog input voltage range of ±4 × V_{REF}/GAIN. At the nominal V_{REF} of +2.5 V and a gain of 1, the AIN2 input voltage range is ±10 V.
19	$\overline{TFS}$	Transmit Frame Synchronization. Active low logic input used to write serial data to the device with serial data expected after the falling edge of this pulse. In the self-clocking mode, the serial clock becomes active after $\overline{TFS}$ goes low. In the external clocking mode, $\overline{TFS}$ must go low before the first bit of the data word is written to the part.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Pin	Mnemonic	Function
20	$\overline{RFS}$	Receive Frame Synchronization. Active low logic input used to access serial data from the device. In the self-clocking mode, the SCLK and SDATA lines both become active after $\overline{RFS}$ goes low. In the external clocking mode, the SDATA line becomes active after $\overline{RFS}$ goes low.
21	$\overline{DRDY}$	Logic output. A falling edge indicates that a new output word is available for transmission. The $\overline{DRDY}$ pin will return high upon completion of transmission of a full output word. $\overline{DRDY}$ is also used to indicate when the AD7712 has completed its on-chip calibration sequence.
22	SDATA	Serial Data. Input/Output with serial data being written to the control register or accessed from the data registers. During a read operation, serial data becomes active after $\overline{RFS}$ goes low. During a write operation, valid serial data is expected on the rising edges of SCLK when $\overline{TFS}$ is low.
23	DV_{DD}	Digital Supply Voltage, +5 V. DV_{DD} should never exceed AV_{DD} by more than 0.3 V. If DV_{DD} powers up before AV_{DD}, or if DV_{DD} can exceed AV_{DD} by more than 0.3 V at any other time, a Schottky diode should be placed between the two pins.
24	DGND	Ground reference point for digital circuitry.

2

TERMINOLOGY

INTEGRAL NONLINEARITY

This is the maximum deviation of any code from a straight line passing through the endpoints of the transfer function. The endpoints of the transfer function are zero scale (not to be confused with bipolar zero), a point 0.5 LSB below the first code transition (000 . . . 000 to 000 . . . 001) and full scale, a point 0.5 LSB above the last code transition (111 . . . 110 to 111 . . . 111). The error is expressed as a percentage of full scale.

POSITIVE FULL-SCALE ERROR

Positive full-scale error is the deviation of the last code transition (111 . . . 110 to 111 . . . 111) from the ideal input full-scale voltage. For AIN1(+), the ideal full-scale input voltage is (AIN1(−) + V_{REF}/GAIN −3/2 LSBs); for AIN2, the ideal full-scale voltage is +4 × V_{REF}/GAIN −3/2 LSBs. Positive Full-Scale Error applies to both unipolar and bipolar analog input ranges.

UNIPOLAR OFFSET ERROR

Unipolar offset error is the deviation of the first code transition from the ideal input voltage. For AIN1(+), the ideal input voltage is (AIN1(−) + 0.5 LSB); for AIN2, the ideal input is 0.5 LSB when operating in the unipolar mode.

BIPOLAR ZERO ERROR

This is the deviation of the midscale transition (0111 . . . 111 to 1000 . . . 000) from the ideal input voltage. For AIN1(+), the ideal input voltage is (AIN1(−) − 0.5 LSB); for AIN2, the ideal input voltage is −0.5 LSB when operating in the bipolar mode.

BIPOLAR NEGATIVE FULL-SCALE ERROR

This is the deviation of the first code transition from the ideal input voltage. For AIN1(+), the ideal input voltage is (AIN1(−) −V_{REF}/GAIN + 0.5 LSB); for AIN2, the ideal input voltage is (−4 × V_{REF}/GAIN+0.5 LSB) when operating in the bipolar mode.

POSITIVE FULL-SCALE OVERRANGE

Positive Full-Scale Overrange is the amount of overhead available to handle input voltages on AIN1(+) input greater than (AIN1(−) +V_{REF}/GAIN) or on AIN2 of greater than +4 × V_{REF}/GAIN (for example, noise peaks or excess voltages due to system gain errors in system calibration routines) without introducing errors due to overloading the analog modulator or to overflowing the digital filter.

NEGATIVE FULL-SCALE OVERRANGE

This is the amount of overhead available to handle voltages on AIN1(+) below (AIN(−) −V_{REF}/GAIN) or on AIN2 below −4 × V_{REF}/GAIN without overloading the analog modulator or overflowing the digital filter. Note that the analog input will accept negative voltage peaks on AIN1(+) even in the unipolar mode provided that AIN1(+) is greater than AIN1(−) and greater than V_{SS} −30 mV.

OFFSET CALIBRATION RANGE

In the system calibration modes, the AD7712 calibrates its offset with respect to the analog input. The offset calibration range specification defines the range of voltages that the AD7712 can accept and still calibrate offset accurately.

FULL-SCALE CALIBRATION RANGE

This is the range of voltages that the AD7712 can accept in the system calibration mode and still calibrate full-scale correctly.

INPUT SPAN

In system calibration schemes, two voltages applied in sequence to the AD7712's analog input define the analog input range. The input span specification defines the minimum and maximum input voltages from zero to full scale that the AD7712 can accept and still calibrate gain accurately.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

A write to the device with the A0 input low writes data to the control register. A read to the device with the A0 input low accesses the contents of the control register.

MD2	MD1	MD0	G2	G1	G0	CH	PD	WL	X	BO	B/U

FS11	FS10	FS9	FS8	FS7	FS6	FS5	FS4	FS3	FS2	FS1	FS0

X = Don't Care.

Operating Mode

MD2	MD1	MD0	Operating Mode
0	0	0	Normal Mode. This is the normal mode of operation of the device whereby a read to the device accesses data from the data register. This is the default condition of these bits after the internal power-on reset.
0	0	1	Activate Self-Calibration. This activates self-calibration on the channel selected by CH. This is a one-step calibration sequence, and when complete the part returns to Normal Mode. The $\overline{DRDY}$ output indicates when this self-calibration is complete. For this calibration type, the zero scale calibration is done internally on AGND and the full-scale calibration is done internally on V_{REF}.
0	1	0	Activate System Calibration. This activates system calibration on the channel selected by CH. This is a two-step calibration sequence, with the zero scale calibration done first on the selected input channel and $\overline{DRDY}$ indicating when this zero scale calibration is complete. The part returns to Normal Mode at the end of this first step in the two-step sequence.
0	1	1	Activate System Calibration. This is the second step of the system calibration sequence with full-scale calibration being performed on the selected input channel. Once again, $\overline{DRDY}$ indicates when the full-scale calibration is complete. When this calibration is complete, the part returns to Normal Mode.
1	0	0	Activate System Offset Calibration. This activates system offset calibration on the channel selected by CH. This is a one-step calibration sequence; the part returns to Normal Mode with $\overline{DRDY}$ indicating when this system offset calibration is complete. For this calibration type, the zero scale calibration is done on the selected input channel and the full-scale calibration is done internally on V_{REF}.
1	0	1	Activate Background Calibration. This activates background calibration on the channel selected by CH. If the background calibration mode is on, then the AD7712 provides continuous self-calibration of the reference and AGND. This calibration takes place as part of the conversion sequence, extending the conversion time and reducing the word rate by a factor of six. Its major advantage is that the user does not have to worry about recalibrating the device when there is a change in the ambient temperature. In this mode, AGND and V_{REF}, as well as the analog input voltage, are continuously monitored and the calibration registers of the device are automatically updated, if necessary.
1	1	0	Read/Write Zero Scale Calibration Coefficients. A read to the device with A0 high accesses the contents of the zero scale calibration coefficients of the channel selected by CH. A write to the device with A0 high writes data to the zero scale calibration coefficients of the channel selected by CH. The word length for reading and writing these coefficients is 24 bits, regardless of the status of the WL bit of the control register.
1	1	1	Read/Write Full-Scale Calibration Coefficients. A read to the device with A0 high accesses the contents of the full-scale calibration coefficients of the channel selected by CH. A write to the device with A0 high writes data to the full-scale calibration coefficients of the channel selected by CH. The word length for reading and writing these coefficients is 24 bits regardless, of the status of the WL bit of the control register.

Filter Selection (FS11–FS0)

The on-chip digital filter provides a $Sinc^3$ (or $(Sinx/x)^3$ filter response. The 12 bits of data programmed into these bits determine the filter cutoff frequency, the position of the first notch of the filter and the data rate for the part. In association with the gain selection, it also determines the output noise (and hence the effective resolution) of the device.

The first notch of the filter occurs at a frequency determined by the relationship: filter first notch frequency = $(f_{CLK\ IN}/512)/code$ where *code* is the decimal equivalent of the code in bits FS0 to FS11 and is in the range 19 to 2,000. With the nominal $f_{CLK\ IN}$ of 10 MHz, this results in a first notch frequency range from 9.76 Hz to 1.028 kHz. To ensure correct operation of the AD7712, the value of the code loaded to these bits must be within this range. Failure to do this will result in unspecified operation of the device.

Changing the filter notch frequency, as well as the selected gain, impacts resolution. Tables I and II and Figure 2 show the effect of the filter notch frequency and gain on the effective resolution of the AD7712. The output data rate (or effective conversion time) for the device is equal to the frequency selected for the first notch of the filter. For example, if the first notch of the filter is selected at 50 Hz, then a new word is available at a 50 Hz rate or every 20 ms. If the first notch is at 1 kHz, a new word is available every 1 ms.

The settling time of the filter to a full-scale step input change is worst case 4× the data rate. For example, with the first filter notch at 50 Hz, the settling time of the filter to a full-scale step input change is 80 ms max. If the first notch is at 1 kHz, the settling time of the filter to a full-scale input step is 4 ms max.

The −3 dB frequency is determined by the programmed first notch frequency according to the relationship: filter −3 dB frequency = 0.262 × first notch frequency.

Table I shows the output rms noise for some typical notch and −3 dB frequencies. The numbers given are for the bipolar input ranges with a V_{REF} of +2.5 V. The numbers in Table I are guaranteed by a combination of testing, characterization and design. The output noise from the part comes from two sources, the quantization noise from the analog-to-digital conversion process and device noise. Device noise is independent of gain and essentially flat across the frequency spectrum. Quantization noise is ratiometric to the input full-scale (and hence gain) and its frequency response is shaped by the modulator.

Looking at Table I, as the cutoff frequency increases, the output noise increases because more of the quantization noise of the part comes through to the output and, hence, the output noise increases with increasing −3 dB frequencies. For the lower notch settings, the output noise is dominated by the device noise and, hence, altering the gain has little effect on the output noise. At higher notch frequencies, the quantization noise dominates the output noise and, in this case, the output noise tends to decrease with increasing gain.

Since the output noise comes from two sources, the effective resolution of the device (i.e., the ratio of the output rms noise to the input full scale) does not remain constant with increasing gain or with increasing bandwidth. Table II shows the same table as Table I except that the output is now expressed in terms of effective resolution (the magnitude of the rms noise with respect to 2 × V_{REF}/GAIN, i.e., the input full scale). It is possible to do post filtering on the device to improve the output data rate for a given −3 dB frequency and also to reduce further the output noise (see Digital Filtering section).

Figure 2 gives similar information to that outlined in Table I. In this plot, the output rms noise is shown for the full range of available cutoff frequencies rather than for some typical cutoff frequencies as in Tables I and II. The numbers given in this plot are typical values.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Table I. Output Noise vs. Gain and First Notch Frequency

First Notch of Filter and O/P Data Rate[1]	Output RMS Noise (μV)								
	−3 dB Frequency	Gain of 1	Gain of 2	Gain of 4	Gain of 8	Gain of 16	Gain of 32	Gain of 64	Gain of 128
10 Hz[2]	2.62 Hz	1.7	0.84	0.60	0.42	0.42	0.42	0.42	0.42
25 Hz[2]	6.55 Hz	3.4	1.7	1.2	0.60	0.60	0.60	0.60	0.60
30 Hz[2]	7.86 Hz	3.4	2.4	1.2	0.84	0.84	0.60	0.60	0.60
50 Hz[2]	13.1 Hz	9.5	4.8	2.4	1.7	1.2	0.84	0.84	0.84
60 Hz[2]	15.72 Hz	13.5	6.7	3.4	1.7	1.2	1.2	0.84	0.84
100 Hz[3]	26.2 Hz	54	27	13.5	6.7	3.4	1.7	1.7	1.2
250 Hz[3]	65.5 Hz	432	216	108	54	27	13.5	6.7	4.8
500 Hz[3]	131 Hz	2.4×10^3	1.2×10^3	610	305	153	76	38	19
1 kHz[3]	262 Hz	13.8×10^3	6.9×10^3	3.4×10^3	1.7×10^3	863	432	216	108

NOTES
[1]The default condition (after the internal power-on reset) for the first notch of filter is 60 Hz.
[2]For these filter notch frequencies, the output rms noise is primarily independent of the value of the reference voltage. Therefore, increasing the reference voltage will give an increase in the effective resolution of the device (i.e., the ratio of the rms noise to the input full scale is increased since the output rms noise remains constant as the input full-scale increases).
[3]For these filter notch frequencies, the output rms noise is proportional to the value of the reference voltage.

Table II. Effective Resolution vs. Gain and First Notch Frequency

First Notch of Filter and O/P Data Rate	Effective Resolution[1] (Bits)								
	−3 dB Frequency	Gain of 1	Gain of 2	Gain of 4	Gain of 8	Gain of 16	Gain of 32	Gain of 64	Gain of 128
10 Hz	2.62 Hz	21.5	21.5	21	20.5	19.5	18.5	17.5	16.5
25 Hz	6.55 Hz	20.5	20.5	20	20	19	18	17	16
30 Hz	7.86 Hz	20.5	20	20	19.5	18.5	18	17	16
50 Hz	13.1 Hz	19	19	19	18.5	18	17.5	16.5	15.5
60 Hz	15.72 Hz	18.5	18.5	18.5	18.5	18	17	16.5	15.5
100 Hz	26.2 Hz	16.5	16.5	16.5	16.5	16.5	16.5	15.5	15
250 Hz	65.5 Hz	13.5	13.5	13.5	13.5	13.5	13.5	13.5	13
500 Hz	131 Hz	11	11	11	11	11	11	11	11
1 kHz	262 Hz	8.5	8.5	8.5	8.5	8.5	8.5	8.5	8.5

NOTE
[1]Effective resolution is defined as the magnitude of the output rms noise to the input full scale (i.e., $2 \times V_{REF}$/GAIN). The above table applies for a V_{REF} of +2.5 V and resolution numbers are rounded to the nearest 0.5 LSB.

PRELIMINARY TECHNICAL DATA

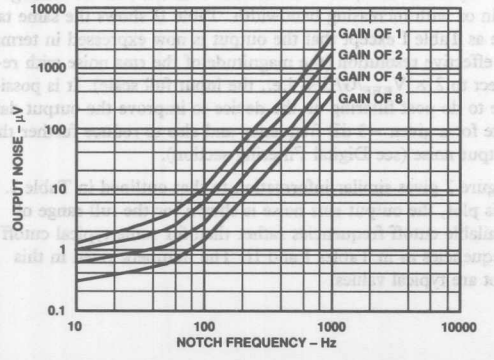

Figure 2a. Plot of Output Noise vs. Gain and Notch Frequency (Gains of 1 to 8)

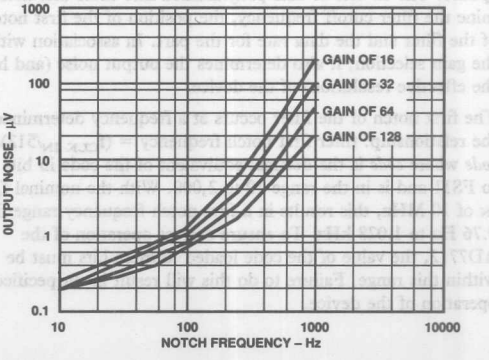

Figure 2b. Plot of Output Noise vs. Gain and Notch Frequency (Gains of 16 to 128)

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

CIRCUIT DESCRIPTION

The AD7712 is a sigma-delta A/D converter with on-chip digital filtering, intended for the measurement of wide dynamic range, low frequency signals such as those in industrial control or process control applications. It contains a sigma-delta (or charge-balancing) ADC, a calibration microcontroller with on-chip static RAM, a clock oscillator, a digital filter and a bidirectional serial communications port.

The part contains two analog input channels, one programmable gain differential input and one programmable gain high-level single-ended input. The gain range on both inputs is from 1 to 128. For the AIN1 input, this means that the input can accept unipolar signals of between 0 to +20 mV and 0 to +2.5 V or bipolar signals in the range from ±20 mV to ±2.5 V when the reference input voltage equals +2.5 V. The input voltage range for the AIN2 input is $\pm 4 \times V_{REF}/GAIN$ and is ±10 V with the nominal reference of +2.5 V and a gain of 1. The input signal to the selected analog input channel is continuously sampled at a rate determined by the frequency of the master clock, CLK IN, and the selected gain (see Table III). A charge balancing A/D converter (Sigma-Delta Modulator) converts the sampled signal into a digital pulse train whose duty cycle contains the digital information. The programmable gain function on the analog input is also incorporated in this sigma-delta modulator with the input sampling frequency being modified to give the higher gains. A sinc^3 digital low pass filter processes the output of the sigma-delta modulator and updates the output register at a rate determined by the first notch frequency of this filter. The output data can be read from the serial port randomly or periodically at any rate up to the output register update rate. The first notch of this digital filter (and hence its −3 dB frequency) can be programmed via an on-chip control register. The programmable range for this first notch frequency is from 9.76 Hz to 1.028 kHz, giving a programmable range for the −3 dB frequency of 2.58 Hz to 269 Hz.

The basic connection diagram for the part is shown in Figure 3. This shows the AD7712 in the external clocking mode with both the AV_{DD} and DV_{DD} pins of the AD7712 being driven from the analog +5 V supply. Some applications will have separate supplies for both AV_{DD} and DV_{DD}, and in some of these cases, the analog supply will exceed the +5 V digital supply (see Power Supplies and Grounding section).

The AD7712 provides a number of calibration options which can be programmed via the on-chip control register. A calibration cycle may be initiated at any time by writing to this control register. The part can perform self-calibration using the on-chip calibration microcontroller and SRAM to store calibration parameters. Other system components may also be included in the calibration loop to remove offset and gain errors in the input channel using the system calibration mode. Another option is a background calibration mode where the part continuously performs self-calibration and updates the calibration coefficients. Once the part is in this mode, the user does not have to worry about issuing periodic calibration commands to the device or asking the device to recalibrate when there is a change in the ambient temperature or power supply voltage.

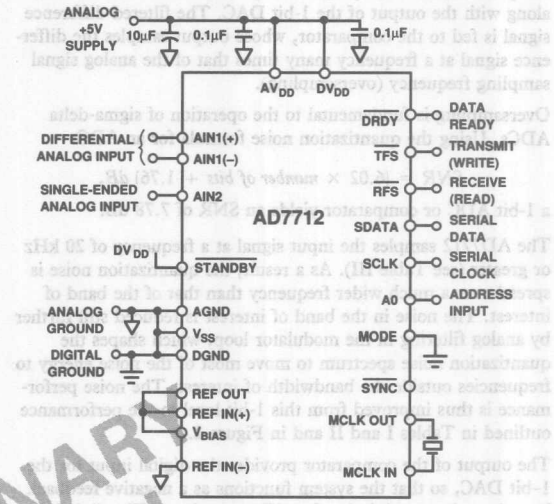

Figure 3. Basic Connection Diagram

The AD7712 gives the user access to the on-chip calibration registers allowing the microprocessor to read the device's calibration coefficients and also to write its own calibration coefficients to the part. This gives the microprocessor much greater control over the AD7712's calibration procedure. It also means that the user can verify that the device has performed its calibration correctly by comparing the coefficients after calibration with prestored values in E^{2}PROM.

The AD7712 can be operated in single supply systems provided that the analog input voltage on the AIN1 input does not go more negative than 30 mV. For larger bipolar signals on the AIN1 input, a V_{SS} of −5 V is required by the part. For battery operation, the AD7712 also offers a software programmable standby mode that reduces idle power consumption to typically 50 µW.

THEORY OF OPERATION

The general block diagram of a sigma-delta ADC is shown in Figure 4. It contains the following elements.

1. A sample-hold amplifier.
2. A differential amplifier or subtractor.
3. An analog low-pass filter.
4. A 1-bit A/D converter (comparator).
5. A 1-bit DAC.
6. A digital low-pass filter.

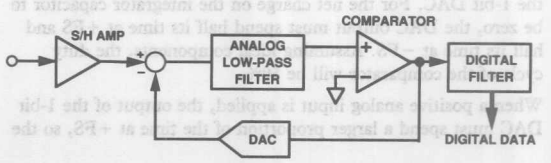

Figure 4. General Sigma-Delta ADC

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

along with the output of the 1-bit DAC. The filtered difference signal is fed to the comparator, whose output samples the difference signal at a frequency many times that of the analog signal sampling frequency (oversampling).

Oversampling is fundamental to the operation of sigma-delta ADCs. Using the quantization noise formula for an ADC:

$$SNR = (6.02 \times number\ of\ bits + 1.76)\ dB,$$

a 1-bit ADC or comparator yields an SNR of 7.78 dB.

The AD7712 samples the input signal at a frequency of 20 kHz or greater (see Table III). As a result, the quantization noise is spread over a much wider frequency than that of the band of interest. The noise in the band of interest is reduced still further by analog filtering in the modulator loop, which shapes the quantization noise spectrum to move most of the noise energy to frequencies outside the bandwidth of interest. The noise performance is thus improved from this 1-bit level to the performance outlined in Tables I and II and in Figure 2.

The output of the comparator provides the digital input for the 1–bit DAC, so that the system functions as a negative feedback loop that tries to minimize the difference signal. The digital data that represents the analog input voltage is contained in the duty cycle of the pulse train appearing at the output of the comparator. It can be retrieved as a parallel binary data word using a digital filter.

Sigma-delta ADCs are generally described by the order of the analog low pass filter. A simple example of a first order sigma-delta ADC is shown in Figure 5. This contains only a first-order low pass filter or integrator. It also illustrates the derivation of the alternative name for these devices : Charge Balancing ADCs.

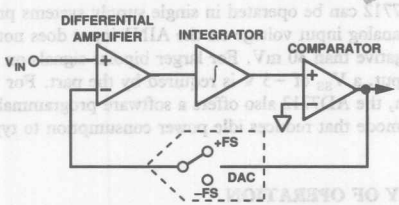

Figure 5. Basic Charge Balancing ADC

It consists of a differential amplifier (whose output is the difference between the analog input and the output of a 1-bit DAC), an integrator and a comparator. The term, "charge-balancing," comes from the fact that this system is a negative feedback loop that tries to keep the net charge on the integrator capacitor at zero by balancing charge injected by the input voltage with charge injected by the 1-bit DAC. When the analog input is zero, the only contribution to the integrator output comes from the 1-bit DAC. For the net charge on the integrator capacitor to be zero, the DAC output must spend half its time at +FS and half its time at −FS. Assuming ideal components, the duty cycle of the comparator will be 50%.

When a positive analog input is applied, the output of the 1-bit DAC must spend a larger proportion of the time at +FS, so the voltage is applied, the duty cycle decreases.

The AD7712 uses a second-order sigma-delta modulator and a digital filter that provides a rolling average of the sampled output. After power-up, or if there is a step change in the input voltage, there is a settling time that must elapse before valid data is obtained.

Input Sample Rate

The modulator sample frequency for the device remains at $f_{CLK\ IN}/512$ (20 kHz @ $f_{CLK\ IN}$ = 10 MHz) regardless of the selected gain. However, gains greater than ×1 are achieved by a combination of multiple input samples per modulator cycle and a scaling of the ratio of reference capacitor to input capacitor. As a result of the multiple sampling, the input sample rate of the device varies with the selected gain (see Table III). The effective input impedance is $1/C \cdot f_S$ where C is the input sampling capacitance and f_S is the input sample rate.

Table III. Input Sampling Frequency vs. Gain

Gain	Input Sampling Frequency (f_S)
1	$f_{CLK\ IN}/512$ (20 kHz @ $f_{CLK\ IN}$ = 10 MHz)
2	$2 \times f_{CLK\ IN}/512$ (40 kHz @ $f_{CLK\ IN}$ = 10 MHz)
4	$4 \times f_{CLK\ IN}/512$ (80 kHz @ $f_{CLK\ IN}$ = 10 MHz)
8	$4 \times f_{CLK\ IN}/512$ (160 kHz @ $f_{CLK\ IN}$ = 10 MHz)
16	$4 \times f_{CLK\ IN}/512$ (160 kHz @ $f_{CLK\ IN}$ = 10 MHz)
32	$4 \times f_{CLK\ IN}/512$ (160 kHz @ $f_{CLK\ IN}$ = 10 MHz)
64	$4 \times f_{CLK\ IN}/512$ (160 kHz @ $f_{CLK\ IN}$ = 10 MHz)
128	$4 \times f_{CLK\ IN}/512$ (160 kHz @ $f_{CLK\ IN}$ = 10 MHz)

DIGITAL FILTERING

The AD7712's digital filter behaves like a similar analog filter, with a few minor differences.

First, since digital filtering occurs after the A-to-D conversion process, it can remove noise injected during the conversion process. Analog filtering cannot do this.

On the other hand, analog filtering can remove noise superimposed on the analog signal before it reaches the ADC. Digital filtering cannot do this and noise peaks riding on signals near full-scale have the potential to saturate the analog modulator and digital filter, even though the average value of the signal is within limits. To alleviate this problem, the AD7712 has overrange headroom built into the sigma-delta modulator and digital filter which allows overrange excursions of 5% above the analog input range. If noise signals are larger than this, consideration should be given to analog input filtering, or to reducing the input channel voltage so that its full scale is half that of the analog input channel full scale. This will provide an overrange capability greater than 100% at the expense of reducing the dynamic range by 1 bit (50%).

Filter Characteristics

The cutoff frequency of the digital filter is determined by the value loaded to bits FS0 to FS11 in the control register. At the maximum clock frequency of 10 MHz, the minimum cutoff frequency of the filter is 2.58 Hz while the maximum programmable cutoff frequency is 269Hz.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Figure 6 shows the filter frequency response for a cutoff frequency of 2.62 Hz which corresponds to a first filter notch frequency of 10 Hz. This is a $(\sin x/x)^3$ response (also called sinc^3) that provides >100 dB of 50 Hz and 60 Hz rejection. Programming a different cutoff frequency via FS0–FS11 does not alter the profile of the filter response, it changes the frequency of the notches as outlined in the Control Register section.

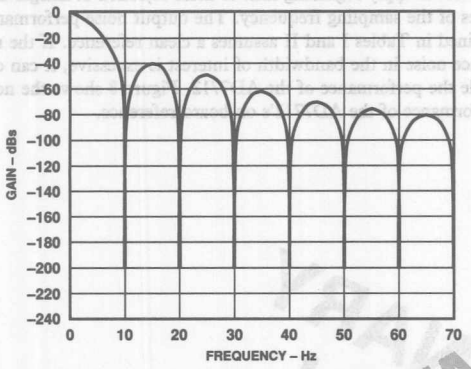

Figure 6. Frequency Response of AD7712 Filter

Since the AD7712 contains this on-chip, low pass filtering, there is a settling time associated with step function inputs and data on the output will be invalid after a step change until the settling time has elapsed. The settling time depends upon the notch frequency chosen for the filter. The output data rate equates to this filter notch frequency and the settling time of the filter to a full-scale step input is 4 times the output data period. In applications using both input channels, the settling time of the filter must be allowed to elapse before data from the second channel is accessed.

Post Filtering

The on-chip modulator provides samples at a 20 kHz output rate. The on-chip digital filter decimates these samples to provide data at an output rate which corresponds to the programmed first notch frequency of the filter. Since the output data rate exceeds the Nyquist criterion, the output rate for a given bandwidth will satisfy most application requirements. However, there may be some applications which require a higher data rate for a given bandwidth and noise performance. Applications which need this higher data rate will require some post filtering following the digital filter of the AD7712.

For example, if the required bandwidth is 7.86 Hz but the required update rate is 100 Hz, the data can be taken from the AD7712 at the 100 Hz rate giving a −3 dB bandwidth of 26.2 Hz. Post filtering can be applied to this to reduce the bandwidth and output noise, to the 7.86 Hz bandwidth level, while maintaining an output rate of 100 Hz.

Post filtering can also be used to reduce the output noise from the device for bandwidths below 2.62 Hz. At a gain of 128, the output rms noise is 420 nV. This is essentially device noise or white noise, and since the input is chopped, the noise has a flat frequency response. By reducing the bandwidth below 2.62 Hz, the noise in the resultant passband can be reduced. A reduction in bandwidth by a factor of 2 results in a $\sqrt{2}$ reduction in the output rms noise. This additional filtering will result in a longer settling time.

Antialias Considerations

The digital filter does not provide any rejection at integer multiples of the modulator sample frequency (n × 20 kHz, where n = 1, 2, 3 . . .). This means that there are frequency bands, $\pm f_{3\ dB}$ wide ($f_{3\ dB}$ is cutoff frequency selected by FS0 to FS11) where noise passes unattenuated to the output. However, due to the AD7712's high oversampling ratio, these bands occupy only a small fraction of the spectrum and most broadband noise is filtered. In any case, because of the high oversampling ratio a simple, RC, single pole filter is generally sufficient to attenuate the signals in these bands on the analog input and thus provide adequate antialiasing filtering.

ANALOG INPUT FUNCTIONS

Analog Input Ranges

The analog inputs on the AD7712 provide the user with considerable flexibility in terms of analog input voltage ranges. One of the inputs is a differential, programmable gain, input channel which can handle either unipolar or bipolar input signals. The common mode range of this input is from V_{SS} to AV_{DD} provided that the absolute value of the analog input voltage lies between V_{SS} −30 mV and AV_{DD} +30 mV. The second analog input is a single-ended, programmable gain high level input which accepts analog input ranges of 0 to $+4 \times V_{REF}/GAIN$ or $\pm 4 \times V_{REF}/GAIN$.

The input sample rate for the part varies as per Table III. For the AIN1 input, the input sampling capacitance is 15 pF typical. The effective input impedance of this AIN1 input is $1/C \cdot f_S$ and this results in a maximum allowable source impedance of whatever is driving the AIN1 analog input of 10 kΩ to ensure correct charging of the sampling capacitor. The AIN2 input is connected to a restive attenuation network and has a nominal input resistance of 44 kΩ (see Figure 7). The AIN2 input should be driven from a low impedance source.

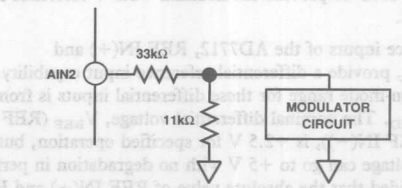

Figure 7. AIN2 Input Attenuation Circuit

The dc input leakage current on the AIN1 input is 10 pA maximum at +25°C. This results in a dc offset voltage developed across the source impedance. However, this dc offset effect can be compensated for by a combination of the differential input capability of the part and its system calibration mode. The dc input current on the AIN2 input depends on the input voltage, For the nominal input voltage range of ±10 V, the input current is ±225 μA typ.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Burn-Out Current

The AIN1(+) input of the AD7712 contains a 100 nA current source which can be turned on/off via the control register. This current source can be used in checking that a transducer has not burnt out or gone open circuit before attempting to take measurements on that channel. If the current is turned on and is allowed flow into the transducer and a measurement of the input voltage on the AIN1 input is taken, it can indicate that the transducer is not functioning correctly. For normal operation, this burn-out current is turned off by writing a 0 to the BO bit in the control register.

Bipolar/Unipolar Inputs

The two analog inputs on the AD7712 can accept either unipolar or bipolar input voltage ranges. Bipolar or unipolar options are chosen by programming the B/U bit of the control register. This programs both channels for either unipolar or bipolar operation. Programming the part for either unipolar or bipolar operation does not change any of the input signal conditioning; it simply changes the data output coding.

The AIN1 input channel is differential and, as a result, the voltage to which the unipolar and bipolar signals are referenced is the voltage on the AIN1(−) input. For example, if AIN1(−) is +1.25 V and the AD7712 is configured for unipolar operation with a gain of 1 and a V_{REF} of +2.5 V, the input voltage range on the AIN1(+) input is +1.25 V to +3.75 V. If AIN1(−) is +1.25 V and the AD7712 is configured for bipolar mode with a gain of 1 and a V_{REF} of +2.5 V, the analog input range on the AIN1(+) input is −1.25 V to +3.75 V. For the AIN2 input, the input signals are referenced to AGND.

REFERENCE INPUT/OUTPUT

The AD7712 contains a temperature compensated +2.5 V reference which has an initial tolerance of ±25 mV. This reference voltage is provided at the REF OUT pin and it can be used as the reference voltage for the part by connecting the REF OUT pin to the REF IN(+) pin. This REF OUT pin is a single-ended output, referenced to AGND, which is capable of providing up to 1 mA to an external load. In applications where REF OUT is connected directly to REF IN(+), REF IN(−) should be tied to AGND to provide the nominal +2.5 V reference for the AD7712.

The reference inputs of the AD7712, REF IN(+) and REF IN(−), provide a differential reference input capability. The common-mode range for these differential inputs is from V_{SS} to AV_{DD}. The nominal differential voltage, V_{REF} (REF IN(+) −REF IN(−)), is +2.5 V for specified operation, but the reference voltage can go to +5 V with no degradation in performance provided that the absolute value of REF IN(+) and REF IN(−) does not exceed its AV_{DD} and V_{SS} limits. REF IN(+) must always be greater than REF IN(−) for correct operation of the AD7712.

Both reference inputs provide a high impedance, dynamic load similar to the AIN1 analog input. The maximum dc input leakage current is 10 pA (±1 μA over temperature) and source resistances will result in gain errors on the part. The reference inputs are switched capacitor inputs with the input capacitance dependent upon the selected gain. For gains of 1 to 8 the input capacitance is 20 pF; for a gain of 16 it is 10 pF; for a gain of 32 it is 5 pF; for a gain of 64 it is 2.5 pF; and for a gain of 128 it is 1.25 pF.

The digital filter of the AD7712 removes noise from the reference input just as it does with the analog input, and the same limitations apply regarding lack of noise rejection at integer multiples of the sampling frequency. The output noise performance outlined in Tables I and II assumes a clean reference. If the reference noise in the bandwidth of interest is excessive, it can degrade the performance of the AD7712. Figure 8 shows the noise performance of the AD7712's on-board reference.

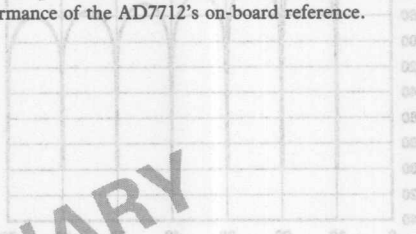

Figure 8. AD7712 Reference Output Noise

V_{BIAS} Input

The V_{BIAS} input determines at what voltage the internal analog circuitry is biased. It essentially provides the return path for analog currents flowing in the modulator and, as such, it should be driven from a low impedance point to minimize errors.

For maximum internal headroom, the V_{BIAS} voltage should be set halfway between AV_{DD} and V_{SS}. The difference between AV_{DD} and (V_{BIAS} + 0.85 × V_{REF}) determines the amount of headroom which the circuit has at the upper end while the difference between V_{SS} and (V_{BIAS} −0.85 × V_{REF}) determines the amount of headroom the circuit has at the lower end. Care should be taken in choosing a V_{BIAS} voltage to ensure that V_{BIAS} ±0.85 × V_{REF} does not exceed the AV_{DD} and V_{SS} limits. For example, with AV_{DD} = +4.75 V, V_{SS} = 0 V and V_{REF} = +2.5 V, the allowable range for the V_{BIAS} voltage is +2.125 V to +2.625 V. With AV_{DD} = +9.5 V, V_{SS} = 0 V and V_{REF} = +5 V, the range for V_{BIAS} is +4.25 V to +5.25 V. With AV_{DD} = +4.75 V, V_{SS} = −4.75 V and V_{REF} = +2.5 V, the V_{BIAS} range is −2.625 V to +2.625 V.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

USING THE AD7712

SYSTEM DESIGN CONSIDERATIONS

The AD7712 operates differently from successive approximation ADCs or integrating ADCs. Since it samples the signal continuously, like a tracking ADC, there is no need for a start convert command. The output register is updated at a rate determined by the first notch of the filter and the output can be read at any time, either synchronously or asynchronously.

Clocking

The AD7712 requires a master clock input, which may be an external TTL/CMOS compatible clock signal applied to the MCLK IN pin with the MCLK OUT pin left unconnected. Alternatively, a crystal of the correct frequency can be connected between MCLK IN and MCLK OUT, in which case the clock circuit will function as a crystal controlled oscillator. For lower clock frequencies, a ceramic resonator may be used instead of the crystal. For these lower frequency oscillators, external capacitors may be required on either the ceramic resonator or on the crystal.

The input sampling frequency, the modulator sampling frequency, the −3 dB frequency, output update rate and calibration time are all directly related to the master clock frequency, $f_{CLK\ IN}$. Reducing the master clock frequency by a factor of 2 will halve the above frequencies and update rate and will double the calibration time.

The current drawn from the DV_{DD} power supply is also directly related to $f_{CLK\ IN}$. Reducing $f_{CLK\ IN}$ by a factor of 2 will halve the DV_{DD} current but will not affect the current drawn from the AV_{DD} power supply.

System Synchronization

If multiple AD7712s are operated from a common master clock, they can be synchronized to update their output registers simultaneously. A falling edge on the $\overline{SYNC}$ input resets the filter and places the AD7712 into a consistent, known state. A common signal to the AD7712s' $\overline{SYNC}$ inputs will synchronize their operation. This would normally be done after each AD7712 has performed its own calibration or has had calibration coefficients loaded to it.

ACCURACY

Sigma-delta ADCs, like VFCs and other integrating ADCs, do not contain any source of nonmonotonicity and inherently offer no missing codes performance. The AD7712 achieves excellent linearity by the use of high quality, on-chip silicon dioxide capacitors, which have a very low capacitance/voltage coefficient. The device also achieves low input drift through the use of chopper stabilized techniques in its input stage. To ensure excellent performance over time and temperature, the AD7712 uses digital calibration techniques that minimize offset and gain error.

Autocalibration

Autocalibration on the AD7712 removes offset and gain errors from the device. A calibration routine should be initiated on the device whenever there is a change in the ambient operating temperature or supply voltage. It should also be initiated if there is a change in the selected channel, gain, filter notch or bipolar/unipolar input range. However, if the AD7712 is in its background calibration mode, the above changes are all automatically taken care of (after the settling time of the filter has been allowed for).

The AD7712 offers self-calibration, system calibration and background calibration facilities. For calibration to occur on the selected channel, the on-chip microcontroller must record the modulator output for two different input conditions. These are "zero scale" and "full-scale" points. With these readings, the microcontroller can calculate the gain slope for the input to output transfer function of the converter. Internally, the part works with a resolution of 33 bits to determine its conversion result of either 16 bits or 24 bits.

Self-Calibration

In the self-calibration mode with a unipolar input range, the zero scale point used in determining the calibration coefficients is AGND and the full-scale point is V_{REF}. The zero scale coefficient is determined by converting an internal AGND node. The full scale coefficient is determined from the span between this AGND conversion and a conversion on an internal V_{REF} node. The self-calibration mode is invoked by writing the appropriate values (0, 0, 1) to the MD2, MD1 and MD0 bits of the control register. In this calibration mode, the AGND node is switched in to the modulator first and a conversion is performed; the V_{REF} node is then switched in and another conversion is performed. When the calibration sequence is complete, the calibration coefficients updated and the filter resettled to the analog input voltage, the $\overline{DRDY}$ output goes low.

For bipolar input ranges in the self-calibrating mode, the sequence is very similar to that just outlined. In this case, the two points which the AD7712 calibrates are midscale (bipolar zero) and positive full scale.

System Calibration

System calibration allows the AD7712 to compensate for system gain and offset errors as well as its own internal errors. System calibration performs the same slope factor calculations as self-calibration but uses voltage values presented by the system to the AIN inputs for the zero and full-scale points. System calibration is a two-step process. The zero scale point must be presented to the converter first. It must be applied to the converter before the calibration step is initiated and remain stable until the step is complete. System calibration is initiated by writing the appropriate values (0, 1, 0) to the MD2, MD1 and MD0 bits of the control register. The $\overline{DRDY}$ output from the device will signal when the step is complete by going low. After the zero scale point is calibrated, the full-scale point is applied and the second step of the calibration process is initiated by again writing the appropriate values (0, 1, 1) to MD2, MD1 and MD0. Again the full-scale voltage must be set up before the calibration is initiated and it must remain stable throughout the calibration step. $\overline{DRDY}$ goes low at the end of this second step to indicate that the system calibration is complete. In the unipolar mode, the system calibration is performed between the two endpoints of the transfer function; in the bipolar mode, it is performed between midscale and positive full scale.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

This two-step system calibration mode offers another feature. After the sequence has been completed, additional offset calibrations can be performed by themselves to adjust the zero reference point to a new system zero reference value. This is achieved by performing the first step of the system calibration sequence (by writing 0, 1, 0 to MD2, MD1, MD0). This will adjust the zero scale or offset point but will not change the slope factor from what was set during a full system calibration sequence.

System Offset Calibration

System offset calibration is a variation of both the system calibration and self-calibration. In this case, the zero scale point for the system is presented to the AIN input of the converter. System offset calibration is initiated by writing 1, 0, 0 to MD2, MD1, MD0. The system zero scale coefficient is determined by converting the voltage applied to the AIN input, while the full-scale coefficient is determined from the span between this AIN conversion and a conversion on an internal V_{REF} node. The zero scale point should be applied to the AIN input for the duration of the calibration sequence. This is a one-step calibration sequence with $\overline{DRDY}$ going low when the sequence is completed. In the unipolar mode, the system offset calibration is performed between the two endpoints of the transfer function; in the bipolar mode, it is performed between midscale and positive full scale.

Background Calibration

The AD7712 also offers a background calibration mode where the part interleaves its calibration procedure with its normal conversion sequence. In the background calibration mode, the same nodes are used as the calibration points as are used in the self-calibration mode (i.e., AGND and V_{REF}). The background calibration mode is invoked by writing 1, 0, 1 to MD2, MD1, MD0 of the control register. When invoked, the background calibration mode reduces the output data rate of the AD7712 by a factor of six. Its advantage is that the part is continually performing calibration and automatically updating its calibration coefficients. As a result, the effects of temperature drift, supply sensitivity and time drift on zero and full scale errors are automatically removed. When the background calibration mode is turned on, the part will remain in this mode until bits MD2, MD1 and MD0 of the control register are changed.

Table IV summarizes the calibration modes and the calibration points associated with them.

Span and Offset Limits

Whenever a system calibration mode is used, there are limits on the amount of offset and span that can be accommodated. The range of input span in both the unipolar and bipolar modes for the AIN1 input has a minimum value of $0.8 \times V_{REF}/GAIN$ and a maximum value of $2.1 \times V_{REF}/GAIN$. For the AIN2 input, these limits are $3.2 \times V_{REF}/GAIN$ and $8.2 \times V_{REF}/GAIN$.

The amount of offset that can be accommodated depends on whether the unipolar or bipolar mode is being used. In unipolar mode, the system calibration modes can handle a maximum offset of $0.25 \times V_{REF}/GAIN$ and a minimum offset of $-(1.05 \times V_{REF}/GAIN)$ on the AIN1 input. This offset range is limited by the requirement that the positive full-scale calibration limit is $\leq 1.05 \times V_{REF}/GAIN$. Thus, the maximum offset ($0.25 \times V_{REF}/GAIN$) plus the minimum span ($0.8 \times V_{REF}/GAIN$) cannot exceed $1.05 \times V_{REF}/GAIN$. For AIN2, the maximum and minimum limits for offset are $V_{REF}/GAIN$ and $-(4.2 \times V_{REF}/GAIN)$, respectively.

In the bipolar mode, the system offset calibration range for AIN1 is restricted to $\pm 0.65 \times V_{REF}/GAIN$. The span range of the converter in bipolar mode is equidistant around the voltage used for the zero scale point. Therefore, the maximum offset $\pm(0.65 \times V_{REF}/GAIN)$ plus half the minimum span $\pm(0.4 \times V_{REF}/GAIN)$ must be less than $\pm(1.05 \times V_{REF}/GAIN)$. If the span is set to $2 \times V_{REF}/GAIN$, the input offset cannot move more than $\pm(0.05 \times V_{REF}/GAIN)$ before the endpoints of the transfer function exceed the input overrange limits $\pm(1.05 \times V_{REF}/GAIN)$. For AIN2, the system offset calibration range is $\pm 2.5 \times V_{REF}/GAIN$.

POWER-UP AND CALIBRATION

On power-up, the AD7712 performs an internal reset which sets the contents of the control register to a known state. However, to ensure correct calibration for the device, a calibration routine should be performed after power-up.

The power dissipation and temperature drift of the AD7712 are low and no warm-up time is required before the initial calibration is performed. However, if an external reference is being used, this reference must have stabilized before calibration is initiated.

Drift Considerations

The AD7712 uses chopper stabilization techniques to minimize input offset drift. Charge injection in the analog switches and dc leakage currents at the sampling node are the primary sources of offset voltage drift in the converter. The dc input leakage current is essentially independent of the selected gain but charge injection effects will increase with increasing gain. As a result, the offset drift numbers will be slightly larger for higher gains. Gain drift within the converter depends primarily upon the temperature tracking of the internal capacitors. It is not affected by leakage currents.

Table IV. Calibration Truth Table

Cal Type	MD2, MD1, MD0	Zero Scale Cal	Full-Scale Cal	Sequence
Self-Cal	0, 0, 1	AGND	V_{REF}	One Step
System Cal	0, 1, 0	AIN		Two Step
System Cal	0, 1, 1		AIN	Two Step
System Offset Cal	1, 0, 0	AIN	V_{REF}	One Step
Background Cal	1, 0, 1	AGND	V_{REF}	One Step

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Measurement errors due to offset drift or gain drift can be eliminated at any time by recalibrating the converter or by operating the part in the background calibration mode. Using the system calibration mode can also minimize offset and gain errors in the signal conditioning circuitry. Integral and differential linearity errors are not significantly affected by temperature changes.

POWER SUPPLIES AND GROUNDING

Since the analog inputs and reference input are differential, most of the voltages in the analog modulator are common-mode voltages. V_{BIAS} provides the return path for most of the analog currents flowing in the analog modulator. As a result, the V_{BIAS} input should be driven from a low impedance to minimize errors due to charging/discharging impedances on this line. When the internal reference is used as the reference source for the part, AGND is the ground return for this reference voltage.

The analog and digital supplies to the AD7712 are independent and separately pinned out to minimize coupling between the analog and digital sections of the device. The digital filter will provide rejection of broadband noise on the power supplies, except at integer multiples of the modulator sampling frequency. The digital supply (DV_{DD}) must never exceed the analog positive supply (AV_{DD}) by more than 0.3 V. Power supply sequencing, therefore, is important. If separate analog and digital supplies are used, care must be taken to ensure that the analog supply is powered up first. If this cannot be ensured, or if DV_{DD} can exceed AV_{DD} at any other time, a Schottky diode should be placed between DV_{DD} and AV_{DD}.

DIGITAL INTERFACE

The AD7712's serial communications port provides a flexible arrangement to allow easy interfacing to industry standard microprocessors, microcontrollers and digital signal processors. A serial read to the AD7712 can access data from the output register, the control register or from the calibration registers. A serial write to the AD7712 can write data to the control register or the calibration registers.

Two different modes of operation are available, optimized for different types of interface where the AD7712 can act either as master in the system (it provides the serial clock) or as slave (an external serial clock can be provided to the AD7712). These two modes, labelled self-clocking mode and external clocking mode, are discussed in detail in the following sections.

Self-Clocking Mode

The AD7712 is configured for its self-clocking mode by tying the MODE pin high. In this mode, the AD7712 provides the serial clock signal used for the transfer of data to and from the AD7712. This self-clocking mode can be used with processors that allow an external device to clock their serial port, including most digital signal processors and microcontrollers such as the 68HC11 and 68HC05. It also allows easy interfacing to serial parallel conversion circuits in systems with parallel data communication, allowing interfacing to 74XX299 Universal Shift registers without any additional decoding. In the case of shift registers, the serial clock line should have a pull-down resistor instead of the pull-up resistor shown in Figure 9 and Figure 10.

Read Operation

Data can be read from either the output register, the control register or the calibration registers. A0 determines whether the data read accesses data from the control register or from the output/calibration registers. This A0 signal must remain valid for the duration of the serial read operation. The function of the $\overline{DRDY}$ line is dependent only on the output update rate of the device and the reading of the output data register. $\overline{DRDY}$ only goes low when a new data word is available in the output data register. It is reset high when the last bit of data (either 16th bit or 24th bit) is read from the output register. If a new data word becomes available to the output register while data is being read from the output register, $\overline{DRDY}$ will not indicate this and the new data word will be lost to the user. $\overline{DRDY}$ is not affected by reading from the control register or the calibration registers.

Data can only be accessed from the output data register when $\overline{DRDY}$ is low. If $\overline{RFS}$ goes low while $\overline{DRDY}$ is high, the SCLK and SDATA lines will not become active until $\overline{DRDY}$ goes low. When $\overline{DRDY}$ goes low, the data word will then be output by the AD7712. If $\overline{RFS}$ goes low with $\overline{DRDY}$ high, no data transfer will take place until $\overline{DRDY}$ does go low. Provided $\overline{RFS}$ stays low for long enough, $\overline{RFS}$ can, in most cases, be brought low at any time with the AD7712 clocking the data into the microprocessor, microcontroller or shift register when its clock and data lines become active. $\overline{DRDY}$ does not have any effect on reading data from the control register or from the calibration registers.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

where all the data is read from the AD7712 in one read operation. Figure 9b shows a situation where the data is read from the AD7712 over a number of read operations. Both read operations show a read from the AD7712's output data register. A read from the control register or calibration registers is similar but in these cases the $\overline{DRDY}$ line is not related to the read function. It can go low at any stage in the read cycle without affecting the read and its status should be ignored.

Figure 9a shows a read operation to the AD7712 where $\overline{RFS}$ remains low for the duration of the data word transmission. For the timing diagram shown, it is assumed that there is a pull up resistor on the SCLK output. With $\overline{DRDY}$ low, the $\overline{RFS}$ input is brought low. $\overline{RFS}$ going low enables the serial clock of the AD7712 and also places the MSB of the word on the serial data line. All subsequent data bits are clocked out on a high to low transition of the serial clock and are valid prior to the following rising edge of this clock. The final active falling edge of SCLK clocks out the LSB and this LSB is valid prior to the final active rising edge of SCLK. Coincident with the next falling edge of SCLK, $\overline{DRDY}$ is reset high. $\overline{DRDY}$ going high turns off the

Figure 9b shows a timing diagram for a read operation where $\overline{RFS}$ returns high during the transmission of the word and returns low again to access the rest of the data word. As before, the waveform for SCLK assumes that there is a pull up resistor on this line. Timing parameters and functions are very similar to that outlined for Figure 9a, but Figure 9b has a number of additional times to show timing relationships when $\overline{RFS}$ returns high in the middle of transferring a word.

$\overline{RFS}$ should return high during a low time of SCLK. On the rising edge of $\overline{RFS}$, the SCLK and SDATA outputs are turned off. $\overline{DRDY}$ remains low and will remain low until all bits of the data word are read from the AD7712, regardless of the number of times $\overline{RFS}$ changes state during the read operation. When $\overline{RFS}$ returns low again, it turns on the SCLK output and activates the SDATA output. The first bit placed on the SDATA line after $\overline{RFS}$ goes low is the same bit as appeared on the bus when $\overline{RFS}$ went high. When the entire word is transmitted, the $\overline{DRDY}$ line will go high turning off the SDATA and SCLK lines as per Figure 9a.

PRELIMINARY TECHNICAL DATA

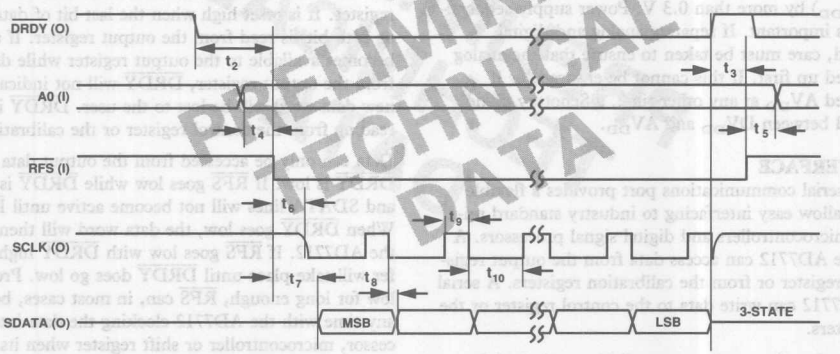

Figure 9a. Self-Clocking Mode, Output Data Read Operation

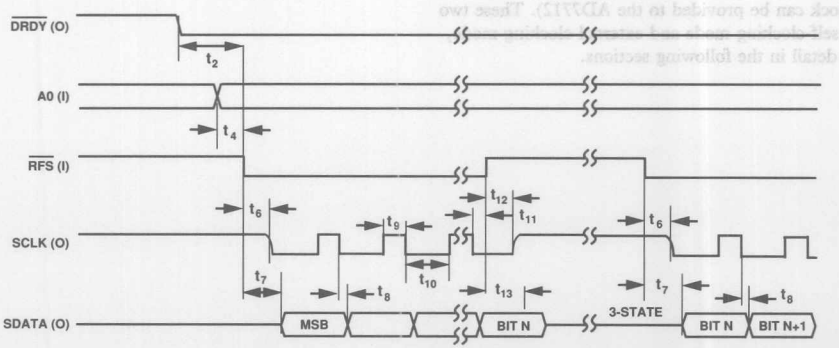

Figure 9b. Self-Clocking Mode, Output Data Read Operation ($\overline{RFS}$ Returns High During Read Operation)

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

registers. In either case, the write operation is not affected by the $\overline{DRDY}$ line and the write operation does not have any effect on the status of $\overline{DRDY}$.

Figure 10a shows a write operation to the AD7712 with $\overline{TFS}$ remaining low for the duration of the write operation. A0 determines whether a write operation transfers data to the control register or to the calibration registers. This A0 signal must remain valid for the duration of the serial write operation. The falling edge of $\overline{TFS}$ enables the internally generated SCLK output. The serial data to be loaded to the AD7712 must be valid on the rising edge of this SCLK signal. Data is clocked into the AD7712 on the rising edge of the SCLK signal with the MSB transferred first. On the last active rising edge of SCLK, the LSB is loaded to the AD7712. Subsequent to the next falling edge of SCLK, the SCLK output is turned off. (The timing diagram of Figure 10a assumes a pull up resistor on the SCLK line.)

Figure 10b shows a timing diagram for a write operation to the AD7712 with $\overline{TFS}$ returning high during the write operation and returning low again to write the rest of the data word. Once

very similar to that outlined for Figure 10a but Figure 10b has a number of additional times to show timing relationships when $\overline{TFS}$ returns high in the middle of transferring a word.

The falling edge of $\overline{TFS}$ again initiates the SCLK output and data to be loaded to the AD7712 must be valid prior to the rising edge of this SCLK signal. The rising edge of $\overline{TFS}$ turns off the SCLK output. $\overline{TFS}$ should return high during the low time of SCLK. When $\overline{TFS}$ returns low again, it turns on the SCLK output. When all data bits have been written to the device, the SCLK output is turned off as per Figure 10a.

External Clocking Mode

The AD7712 is configured for its external clocking mode by tying the MODE pin low. In this mode, SCLK of the AD7712 is configured as an input and an external serial clock must be provided to this SCLK pin. This external clocking mode is designed for direct interface to systems which provide a serial clock output that is synchronized to the serial data output, including microcontrollers such as the 80C51, 87C51, 68HC11 and 68HC05 and most digital signal processors.

PRELIMINARY TECHNICAL DATA

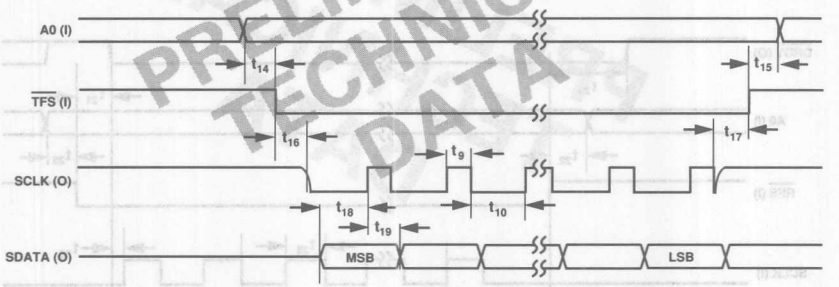

Figure 10a. Self-Clocking Mode, Control/Calibration Register Write Operation

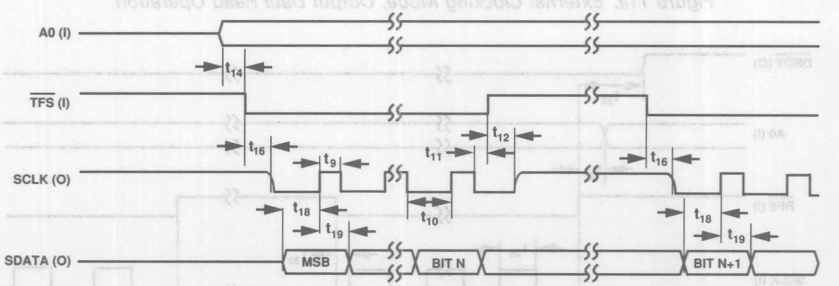

Figure 10b. Self-Clocking Mode, Control/Calibration Register Write Operation ($\overline{TFS}$ Returns High During Write Operation)

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Read Operation

Figures 11a and 11b show timing diagrams for reading from the AD7712 in the external clocking mode. Figure 11a shows a situation where all the data is read from the AD7712 in one read operation. Figure 11b shows a situation where the data is read from the AD7712 over a number of read operations.

As with the self-clocking mode, data can be read from either the output register, the control register or the calibration registers. A0 determines whether the data read accesses data from the control register or from the output/calibration registers. This A0 signal must remain valid for the duration of the serial read operation. The function of the $\overline{DRDY}$ line is dependent only on the output update rate of the device and the reading of the output data register. $\overline{DRDY}$ only goes low when a new data word is available in the output data register. It is reset high when the last bit of data (either 16th bit or 24th bit) is read from the output register. If a new data word becomes available to the output register while data is being read from the output register, $\overline{DRDY}$ will not indicate this and the new data word will be lost to the user. $\overline{DRDY}$ is not affected by reading from the control register or the calibration register.

Data can only be accessed from the output data register when $\overline{DRDY}$ is low. If $\overline{RFS}$ goes low while $\overline{DRDY}$ is high, the SDATA line will not become active until $\overline{DRDY}$ goes low. In this external clocking mode, an external clock is applied to the SCLK input. The receiving device (microprocessor or microcontroller) expects to see valid data on edges of this SCLK signal. However, with $\overline{DRDY}$ high SDATA is not active and no data is transmitted. $\overline{DRDY}$ does not have any effect on reading data from the control register or from the calibration registers.

Figure 11a shows a read operation to the AD7712 where $\overline{RFS}$ remains low for the duration of the data word transmission. With $\overline{DRDY}$ low, the $\overline{RFS}$ input is brought low. The input SCLK signal should be low between read and write operations. $\overline{RFS}$ going low places the MSB of the word to be read on the serial data line. All subsequent data bits are clocked out on a high to low transition of the serial clock and are valid prior to the following rising edge of this clock. The penultimate falling edge of SCLK clocks out the LSB and the final falling edge resets the $\overline{DRDY}$ line high. This rising edge of $\overline{DRDY}$ turns off the serial data output.

Figure 11b shows a timing diagram for a read operation where $\overline{RFS}$ returns high during the transmission of the word and returns low again to access the rest of the data word. Timing parameters and functions are very similar to that outlined for Figure 11a but Figure 11b has a number of additional times to show timing relationships when $\overline{RFS}$ returns high in the middle of transferring a word.

PRELIMINARY TECHNICAL DATA

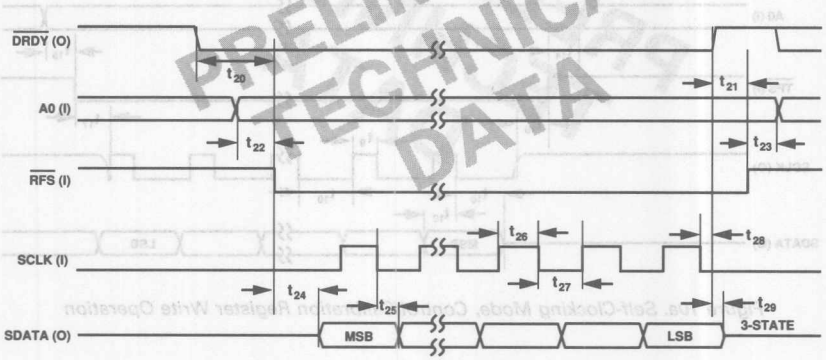

Figure 11a. External Clocking Mode, Output Data Read Operation

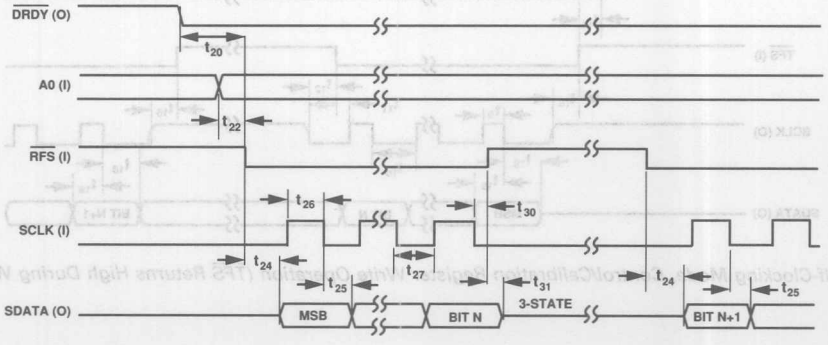

Figure 11b. External Clocking Mode, Output Data Read Operation ($\overline{RFS}$ Returns High During Read Operation)

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

$\overline{RFS}$ should return high during a low time of SCLK. On the rising edge of $\overline{RFS}$, the SDATA output is turned off. $\overline{DRDY}$ remains low and will remain low until all bits of the data word are read from the AD7712, regardless of the number of times $\overline{RFS}$ changes state during the read operation. When $\overline{RFS}$ returns low again, it activates the SDATA output and places the next bit of the data word on the SDATA output. When the entire word is transmitted, the $\overline{DRDY}$ line will go high, turning off the SDATA output as per Figure 11a.

Write Operation

Data can be written to either the control register or calibration registers. In either case, the write operation is not affected by the $\overline{DRDY}$ line and the write operation does not have any effect on the status of $\overline{DRDY}$.

Figure 12a shows a write operation to the AD7712 with $\overline{TFS}$ remaining low for the duration of the write operation. A0 determines whether a write operation transfers data to the control register or to the calibration registers. This A0 signal must remain valid for the duration of the serial write operation. As before, the serial clock line should be low between read and write operations. The serial data to be loaded to the AD7712 must be valid on the high level of the externally applied SCLK signal. Data is clocked into the AD7712 on the high level of this SCLK signal with the MSB transferred first. On the last active rising edge of SCLK, the LSB is loaded to the AD7712.

Figure 12b shows a timing diagram for a write operation to the AD7712 with $\overline{TFS}$ returning high during the write operation and returning low again to write the rest of the data word. Timing parameters and functions are very similar to that outlined for Figure 12a, but Figure 12b has a number of additional times to show timing relationships when $\overline{TFS}$ returns high in the middle of transferring a word.

Data to be loaded to the AD7712 must be valid prior to the rising edge of the SCLK signal. $\overline{TFS}$ should return high during the low time of SCLK . After $\overline{TFS}$ returns low again, the next bit of the data word to be loaded to the AD7712 is clocked in on next high level of the SCLK input. On the last active rising edge of the SCLK input, the LSB is loaded to the AD7712.

SIMPLIFYING THE INTERFACE

In some applications, the user may not require the facility of writing to the on-chip calibration registers. In this case, the serial interface to the AD7712 can be simplified by connecting the $\overline{TFS}$ line to the A0 input of the AD7712. This means that any write to the device will load data to the control register (since A0 is low while $\overline{TFS}$ is low) and any read to the device will access data from the output data register or from the calibration registers (since A0 is high while $\overline{RFS}$ is low). It should be noted that in this arrangement the user does not have the capability of reading from the control register.

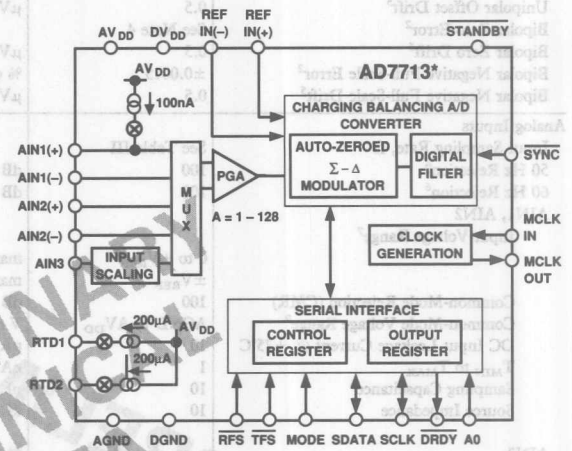
LC²MOS Loop-Powered Signal Conditioning ADC

AD7713*



FEATURES

- Charge Balancing ADC
  - 21 Bits No Missing Codes
  - ±0.0015% Nonlinearity
- Three-Channel Programmable Gain Front End
  - Gains from 1 to 128
  - Two Differential Inputs
  - One Single Ended High Voltage Input
- Low-Pass Filter with Programmable Filter Cutoffs
- Ability to Read/Write Calibration Coefficients
- RTD Excitation Current Sources
- Bidirectional Microcontroller Serial Interface
- Single Supply Operation
- Low Power (3.5 mW typ) with Power-Down Mode (35 μW typ)

APPLICATIONS

- Loop Powered (Smart) Transmitters
- RTD Transducers
- Process Control
- Portable Industrial Instruments

FUNCTIONAL BLOCK DIAGRAM

PRELIMINARY TECHNICAL DATA

GENERAL DESCRIPTION

The AD7713 is a complete analog front end for low frequency measurement applications. The device accepts low level signals directly from a transducer or high level signals ($\pm 4 \times V_{REF}$) and outputs a serial digital word. It employs a sigma-delta conversion technique to realize up to 21 bits of no missing codes performance. The input signal is applied to a proprietary programmable gain front end based around an analog modulator. The modulator output is processed by an on-chip digital filter. The first notch of this digital filter can be programmed via the on-chip control register allowing adjustment of the filter cutoff and settling time.

The part features two differential analog inputs and one single-ended high level analog input as well as a differential reference input. It can be operated from a single supply (AV_{DD} and DV_{DD} at +5 V). The part provides two current sources which can be used to provide excitation in three-wire and four-wire RTD configurations. The AD7713 thus performs all signal conditioning and conversion for a single, dual or three-channel system.

The AD7713 is ideal for use in smart, microcontroller-based systems. Gain settings, signal polarity and RTD current control can be configured in software using the bidirectional serial port. The AD7713 contains self-calibration, system calibration and background calibration options and also allows the user to read and to write the on-chip calibration registers.

CMOS construction ensures very low power dissipation and a software programmable power-down mode reduces the standby power consumption to only 35 μW. The part is available in a 24-pin, 0.3 inch wide, plastic and hermetic dual-in-line package (DIP) as well as a 24-lead small outline (SOIC) package.

PRODUCT HIGHLIGHTS

1. The AD7713 consumes less than 1 mA in total supply current, making it ideal for use in loop-powered systems.
2. The low level programmable gain channels allow the AD7713 to accept input signals directly from a transducer, removing a considerable amount of signal conditioning. To maximize the flexibility of the part, the high level analog input accepts $\pm 4 \times V_{REF}$/GAIN signals. On-chip current sources provide excitation for three-wire and four-wire RTD configurations.
3. No Missing Codes ensures true, usable, 21-bit dynamic range coupled with excellent ±0.0015% accuracy. The effects of temperature drift are eliminated by on-chip self-calibration, which removes zero-scale and full-scale errors.
4. The AD7713 is ideal for microcontroller or DSP processor applications with an on-chip control register which allows control over filter cutoff, input gain, signal polarity and calibration modes. The AD7713 allows the user to read and to write the on-chip calibration registers.

*Patent pending.

Normal Mode	5.5	mW max	$AV_{DD} = DV_{DD}$ = +5 V, $f_{CLK\ IN}$ = 1 MHz; Typically 3.5 mW
Standby (Power-Down) Mode	50	μW max	$AV_{DD} = DV_{DD}$ = +5 V; Typically 35 μW

NOTES

[1]Temperature ranges are as follows: A Version: −40°C to +85°C; S Version: −55°C to +125°C.

[2]Applies after calibration at the temperature of interest.

[3]Positive full-scale error applies to both unipolar and bipolar input ranges.

[4]These errors will be of the order of the output noise of the part as shown in Table I.

[5]Recalibration at any temperature or use of the background calibration mode will remove these drift errors. These numbers are guaranteed by design and/or characterization.

[6]These numbers are guaranteed by design and/or characterization.

[7]The AIN1 and AIN2 analog inputs present a very high impedance dynamic load which varies with clock frequency and input sample rate. The maximum recommended source resistance is 10 kΩ.

[8]V_{REF} = REF IN(+) − REF IN(−).

[9]This common-mode voltage range is allowed provided that the absolute value of the input voltage does not exceed AV_{DD} + 30 mV and AGND − 30 mV.

[10]Sample tested at +25°C to ensure compliance.

[11]After calibration, if the analog input exceeds positive full scale, the converter will output all 1s. If the analog input is less than negative full scale, then the device will output all 0s.

[12]These calibration and span limits apply provided the absolute voltage on the analog inputs does not exceed AV_{DD} or go more negative than AGND − 30 mV.

[13]The offset calibration limit applies to both the unipolar zero point and the bipolar zero point.

[14]Measured at dc and applies in the selected passband. PSRR at 50 Hz will exceed 120 dB with filter notches of 2, 5, 10, 25 or 50 Hz. PSRR at 60 Hz will exceed 120 dB with filter notches of 2, 6, 10, 30 or 60 Hz.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Control Register (24-Bits)

A write to the device with A0 low writes data to the control register. A read to the device with the A0 pin low accesses the contents of the control register.

MD2	MD1	MD0	G2	G1	G0	CH1	CH0	WL	RO	BO	B/U
FS11	FS10	FS9	FS8	FS7	FS6	FS5	FS4	FS3	FS2	FS1	FS0

Operating Mode

MD2	MD1	MD0	Operating Mode
0	0	0	Normal Mode. This is the normal mode of operation of the device whereby a read to the device with A0 high accesses data from the data register. This is the default condition of these bits after the internal power-on reset.
0	0	1	Activate Self-Calibration. This activates self-calibration on the channel selected by CH0 and CH1. This is a one-step calibration sequence and when complete, the part returns to Normal Mode. For this calibration type, the zero-scale calibration is done internally on AGND and the full-scale calibration is done internally on V_{REF}.
0	1	0	Activate System Calibration. This activates system calibration on the channel selected by CH0 and CH1. This is a two-step calibration sequence, with the zero-scale calibration done first on the selected input channel and $\overline{DRDY}$ indicating when this zero-scale calibration is complete. The part returns to Normal Mode at the end of this first step in the two-step sequence.
0	1	1	Activate System Calibration. This is the second step of the system calibration sequence with full-scale calibration being performed on the selected input channel. When this calibration is complete, the part returns to Normal Mode.
1	0	0	Activate System-Offset Calibration. This activates system-offset calibration on the channel selected by CH0 and CH1. This is a one step calibration sequence and when complete the part returns to Normal Mode. For this calibration type, the zero-scale calibration is done on the selected input channel and the full-scale calibration are done internally on V_{REF}.
1	0	1	Activate Background Calibration. This activates background calibration on the channel selected by CH0 and CH1. If the background calibration mode is on, then the AD7713 provides continuous self-calibration of the reference and AGND. This calibration takes place as part of the conversion sequence, extending the conversion time and reducing the word rate by a factor of six. Its major advantage is that the user does not have to worry about recalibrating the device when there is a change in the ambient temperature. In this mode, AGND and V_{REF}, as well as the analog input voltage, are continuously monitored and the calibration registers of the device are updated, if necessary.
1	1	0	Read/Write Zero-Scale Calibration Coefficients. A read to the device with A0 high accesses the contents of the zero-scale calibration coefficients of the channel selected by CH0 and CH1. A write to the device with A0 high writes data to the zero-scale calibration coefficients of the channel selected by CH0 and CH1. The word length for reading and writing these coefficients is 24 bits, regardless of the status of the WL bit of the control register. Note, AIN2 and AIN3 share calibration coefficients.
1	1	1	Read/Write Full-Scale Calibration Coefficients. A read to the device with A0 high accesses the contents of the full-scale calibration coefficients of the channel selected by CH0 and CH1. A write to the device with A0 high writes data to the full-scale calibration coefficients of the channel selected by CH0 and CH1. The word length for reading and writing these coefficients is 24 bits, regardless of the status of the WL bit of the control register. Note, AIN2 and AIN3 share calibration coefficients.

Filter Selection (FS11–FS0)

The on-chip digital filter provides a $Sinc^3$ (or $(Sinx/x)^3$) filter response. The 12 bits of data programmed into these bits determine the filter cutoff frequency, the position of the first notch of the filter and the data rate for the part. In association with the gain selection, it also determines the output noise (and hence the effective resolution) of the device.

The first notch of the filter occurs at a frequency determined by the relationship: filter first notch frequency = $(f_{CLKIN}/512)/$ *code* where *code* is the decimal equivalent of the code in bits FS0 to FS11 and is in the range 19 to 2,000. With the nominal $f_{CLK\ IN}$ of 2 MHz, this results in a first notch frequency range from 1.952 Hz to 205.59 Hz. To ensure correct operation of the AD7713, the value of the code loaded to these bits must be within this range. Failure to do this will result in unspecified operation of the device.

Changing the filter notch frequency, as well as the selected gain, impacts resolution. Tables I and II show the effect of the filter notch frequency and gain on the effective resolution of the AD7713. The output data rate (or effective conversion time) for the device is equal to the frequency selected for the first notch of the filter. For example, if the first notch of the filter is selected at 10 Hz, then a new word is available at a 10 Hz rate or every 100 ms. If the first notch is at 200 Hz, a new word is available every 5 ms.

The settling time of the filter to a full-scale step input change is worst case 4 × the data rate. For example, with the first filter notch at 10 Hz, the settling time of the filter to a full-scale step input change is 400 ms max. If the first notch is at 200 Hz, the settling time of the filter to a full-scale input step is 20 ms max.

The −3 dB frequency is determined by the programmed first notch frequency according to the relationship: filter −3 dB frequency = 0.262 × first notch frequency.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Table I shows the output rms noise for some typical notch and −3 dB frequencies. The numbers given are for the bipolar input ranges with a V_{REF} of +2.5 V. The numbers in Table I are guaranteed by a combination of testing, characterization and design. The output noise from the part comes from two sources: the quantization noise from the analog-to-digital conversion process, and device noise. Device noise is independent of gain and is essentially flat across the frequency spectrum. Quantization noise is ratiometric to the input full scale (and hence gain) and its frequency response is shaped by the modulator.

Looking at Table I, as the cutoff frequency increases, the output noise increases because more of the quantization noise of the part comes through to the output. Hence, the output noise increases with increasing −3 dB frequencies. For the lower notch settings, the output noise is dominated by the device noise and, hence, altering the gain has little effect on the output noise. At higher notch frequencies, the quantization noise dominates the output noise and, in this case, the output noise tends to decrease with increasing gain.

Since the output noise comes from two sources, the effective resolution of the device (i.e., the ratio of the output rms noise to the input full scale) does not remain constant with increasing gain or with increasing bandwidth. Table II shows the same table as Table I except that the output is now expressed in terms of effective resolution (the magnitude of the rms noise with respect to 2 × V_{REF}/GAIN, i.e., the input full scale). It is possible to do post filtering on the device to improve the output data rate for a given −3 dB frequency and also to further reduce the output noise (see DIGITAL FILTERING section).

Table I. Output Noise vs. Gain and First Notch Frequency

First Notch of Filter and O/P Data Rate[1]	−3 dB Frequency	OUTPUT RMS NOISE (μV) GAIN of 1	GAIN of 2	GAIN of 4	GAIN of 8	GAIN of 16	GAIN of 32	GAIN of 64	GAIN of 128
2 Hz[2]	0.52 Hz	1.7	0.84	0.60	0.42	0.42	0.42	0.42	0.42
5 Hz[2]	1.31 Hz	3.4	1.7	1.2	0.60	0.60	0.60	0.60	0.60
6 Hz[2]	1.57 Hz	3.4	2.4	1.2	0.84	0.84	0.60	0.60	0.60
10 Hz[2]	2.62 Hz	9.5	4.8	2.4	1.7	1.2	0.84	0.84	0.84
12 Hz[2]	3.14 Hz	13.5	6.7	3.4	1.7	1.2	1.2	0.84	0.84
20 Hz[3]	5.24 Hz	54	27	13.5	6.7	3.4	1.7	1.7	1.2
50 Hz[3]	13.1 Hz	432	216	108	54	27	13.5	6.7	4.8
100 Hz[3]	26.2 Hz	2.4 × 10^3	1.2 × 10^3	610	305	153	76	38	19
200 Hz[3]	52.4 Hz	13.8 × 10^3	6.9 × 10^3	3.4 × 10^3	1.7 × 10^3	863	432	216	108

NOTES
[1]The default condition (after the internal power-on reset) for the first notch of filter is 12 Hz.
[2]For these filter notch frequencies, the output rms noise is primarily independent of the value of the reference voltage. Therefore, increasing the reference voltage will give an increase in the effective resolution of the device (i.e. the ratio of the rms noise to the input full-scale is increased since the output rms noise remains constant as the input full-scale increases).
[3]For these filter notch frequencies, the output rms noise is proportional to the value of the reference voltage.

Table II. Effective Resolution vs. Gain and First Notch Frequency

First Notch of Filter and O/P Data Rate	−3 dB Frequency	EFFECTIVE RESOLUTION[1] (Bits) GAIN of 1	GAIN of 2	GAIN of 4	GAIN of 8	GAIN of 16	GAIN of 32	GAIN of 64	GAIN of 128
2 Hz	0.52 Hz	21.5	21.5	21	20.5	19.5	18.5	17.5	16.5
5 Hz	1.31 Hz	20.5	20.5	20	20	19	18	17	16
6 Hz	1.57 Hz	20.5	20	20	19.5	18.5	18	17	16
10 Hz	2.62 Hz	19	19	19	18.5	18	17.5	16.5	15.5
12 Hz	3.14 Hz	18.5	18.5	18.5	18.5	18	17	16.5	15.5
20 Hz	5.24 Hz	16.5	16.5	16.5	16.5	16.5	16.5	15.5	15
50 Hz	13.1 Hz	13.5	13.5	13.5	13.5	13.5	13.5	13.5	13
100 Hz	26.2 Hz	11	11	11	11	11	11	11	11
200 Hz	52.4 Hz	8.5	8.5	8.5	8.5	8.5	8.5	8.5	8.5

NOTE
[1]Effective Resolution is defined as the magnitude if the output rms noise to the input full-scale (i.e., 2 × V_{REF}/GAIN). The above table applies for a V_{REF} of +2.5 V and resolution numbers are rounded to the nearest 0.5 LSB.

PRELIMINARY TECHNICAL DATA

PIN FUNCTION DESCRIPTION

Pin	Mnemonic	Function
1	SCLK	Serial Clock. Logic input/output depending on the status of the MODE pin. When MODE is high, the device is in its self-clocking mode and the SCLK pin provides a serial clock output. This SCLK becomes active when $\overline{RFS}$ or $\overline{TFS}$ goes low and it goes high impedance when either $\overline{RFS}$ or $\overline{TFS}$ returns high or when the device has completed transmission of an output word. When MODE is low, the device is in its external clocking mode and the SCLK pin acts as an input. This input serial clock can be a continuous clock with all data being transmitted in a continuous train of pulses. Alternatively, it can be a noncontinuous clock with the information being transmitted to the AD7713 in smaller batches of data.
2	MCLK IN	Master Clock signal for the device. This can be provided in the form of a crystal or external clock. A crystal can be tied across the MCLK IN and MCLK OUT pins. Alternatively, the MCLK IN pin can be driven with a CMOS-compatible clock and MCLK OUT left unconnected. The clock input frequency is nominally 2 MHz.
3	MCLK OUT	When the master clock for the device is a crystal, the crystal is connected between MCLK IN and MCLK OUT.
4	A0	Address Input. With this input low, reading and writing to the device is to the control register. With this input high, access is to either the data register or the calibration registers.
5	$\overline{SYNC}$	Logic Input which allows for synchronization of the digital filters when using a number of AD7713s. It resets the nodes of the digital filter.
6	MODE	Logic Input. When this pin is high, the device is in its self-clocking mode; with this pin low, the device is in its external clocking mode.
7	AIN1(+)	Analog Input Channel 1. Positive input of the programmable-gain differential analog input. The AIN1(+) input is connected to an output current source which can be used to check that an external transducer has burnt out or has gone open circuit. This output current source can be turned on/off via the control register.
8	AIN1(−)	Analog Input Channel 1. Negative input of the programmable gain differential analog input.
9	AIN2(+)	Analog Input Channel 2. Positive input of the programmable gain differential analog input.
10	AIN2(−)	Analog Input Channel 2. Negative input of the programmable gain differential analog input.
11	$\overline{STANDBY}$	Logic Input. Taking this pin low shuts down the internal analog and digital circuitry, reducing power consumption to less than 50 μW.
12	AV_{DD}	Analog Positive Supply Voltage, +5 V to +10 V.
13	RTD1	Constant Current Output. A nominal 200 μA constant current is provided at this pin and this can be used as the excitation current for RTDs. This current can be turned on or off via the control register.
14	REF IN(−)	Reference Input. The REF IN(−) can lie anywhere between AV_{DD} and AGND provided REF IN(+) is greater than REF IN(−).
15	REF IN(+)	Reference Input. The reference input is differential with the proviso that REF IN(+) must be greater than REF IN(−). REF IN(+) can lie anywhere between AV_{DD} and AGND.
16	RTD2	Constant Current Output. A nominal 200 μA constant current is provided at this pin and this can be used as the excitation current for RTDs. This current can be turned on or off via the control register. This second current can be used to eliminate lead resistance errors in three-wire RTD configurations.
17	AIN3	Analog Input Channel 3. High level analog input which accepts an analog input voltage range of $\pm 4 \times V_{REF}/GAIN$. At the nominal V_{REF} of +2.5 V and a gain of 1, the AIN3 input voltage range is ±10 V.
18	AGND	Ground Reference Point for Analog Circuitry.
19	$\overline{TFS}$	Transmit Frame Synchronization. Active low logic input used to write serial data to the device with serial data expected after the falling edge of this pulse. In the Self-Clocking mode, the serial clock becomes active after $\overline{TFS}$ goes low. In the External Clocking mode, $\overline{TFS}$ must go low before the first bit of the data word is written to the part.
20	$\overline{RFS}$	Receive Frame Synchronization. Active low logic input used to access serial data from the device. In the self-clocking mode, the SCLK and SDATA lines both become active after $\overline{RFS}$ goes low. In the external clocking mode, the SDATA line becomes active after $\overline{RFS}$ goes low.
21	$\overline{DRDY}$	Logic Output. A falling edge indicates a new output word is available for transmission. The $\overline{DRDY}$ pin will return high upon completion of transmission of a full output word. $\overline{DRDY}$ is also used to indicate when the AD7713 has completed its on-chip calibration sequence.

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

Pin	Mnemonic	Function
22	SDATA	Serial Data. Input/Output with serial data being written to either the control register or the calibration registers and serial data being accessed from the control register, calibration registers or the data register. During a read operation, serial data becomes active after $\overline{RFS}$ goes low. During a write operation, valid serial data is expected on the rising edges of SCLK when $\overline{TFS}$ is low.
23	DV_{DD}	Digital Supply Voltage, +5 V. DV_{DD} should never exceed AV_{DD} by more than 0.3 V. If DV_{DD} powers up before AV_{DD} or if DV_{DD} can exceed AV_{DD} by more than 0.3 V at any other time, a Schottky diode should be placed between the two pins.
24	DGND	Ground Reference Point for Digital Circuitry.

PIN CONFIGURATION

DIP and SOIC

Table III. Input Sampling Frequency vs. Gain

Gain	Input Sampling Freq (FS)
1	$f_{CLK\ IN}$ /512 (4 kHz @ $f_{CLK\ IN}$ = 2 MHz)
2	2 × $f_{CLK\ IN}$/512 (8 kHz @ $f_{CLK\ IN}$ = 2 MHz)
4	4 × $f_{CLK\ IN}$/512 (16 kHz @ $f_{CLK\ IN}$ = 2 MHz)
8	4 × $f_{CLK\ IN}$/512 (32 kHz @ $f_{CLK\ IN}$ = 2 MHz)
16	4 × $f_{CLK\ IN}$/512 (32 kHz @ $f_{CLK\ IN}$ = 2 MHz)
32	4 × $f_{CLK\ IN}$/512 (32 kHz @ $f_{CLK\ IN}$ = 2 MHz)
64	4 × $f_{CLK\ IN}$/512 (32 kHz @ $f_{CLK\ IN}$ = 2 MHz)
128	4 × $f_{CLK\ IN}$/512 (32 kHz @ $f_{CLK\ IN}$ = 2 MHz)

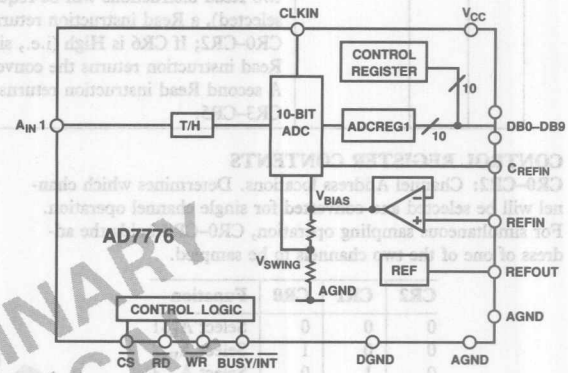
LC²MOS
High Speed 1-, 4- & 8-Channel 10-Bit ADCs
AD7776/AD7777/AD7778*

FEATURES
AD7776: Single Channel
AD7777: 4-Channel
AD7778: 8-Channel
Fast 10-Bit 1.75 μs ADC
+5 V Only
Reference Conversion Option
Fast Interface Port
Power-Down Mode

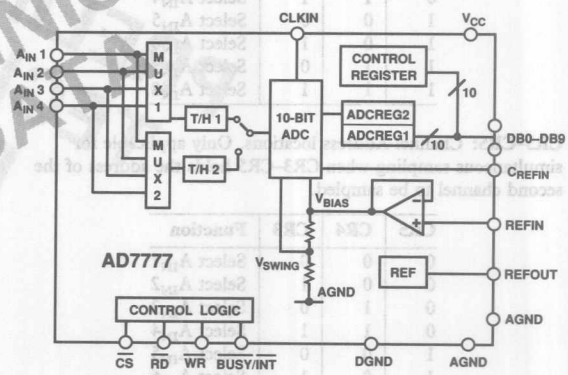
APPLICATIONS
HDD Servos
Instrumentation

GENERAL DESCRIPTION

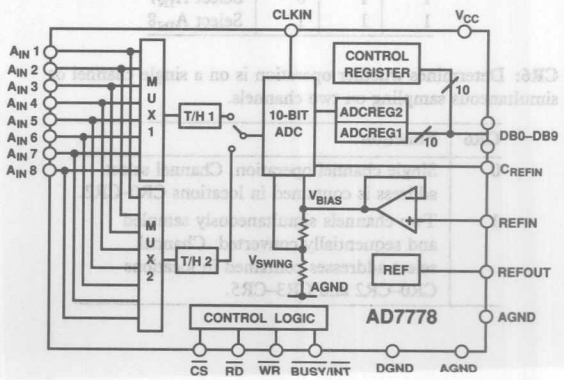
The AD7776, AD7777 and AD7778 are a family of high speed multichannel, 10-bit ADCs primarily intended for use in R/W head positioning servos found in high density hard disc drives. They have unique input signal conditioning features which make them ideal for use in such single supply applications.



By setting a bit in a control register within both the four-channel version, AD7777, and eight-channel version, AD7778, the input channels can either be independently sampled or any two channels of choice can be simultaneously sampled. For all versions an input signal of the form $V_{BIAS} \pm V_{SWING}$ is expected. The voltage V_{BIAS} is the offset of the ADC's midpoint code from ground and is supplied either by an onboard reference available to the user (REFOUT) or by an external voltage reference applied to REFIN. The full-scale range (FSR) of the ADC is equal to $2V_{SWING}$ where V_{SWING} is nominally equal to REFIN/2. Additionally, when placed in the Calibration Mode, the value of REFIN is converted. This allows the channel offset(s) to be measured.



Control register loading and ADC register reading, channel select and conversion start are under the control of the μP. The two's complemented coded ADCs are easily interfaced to a standard 16-bit MPU bus via their 10-bit data port and standard microprocessor control lines.



They are fabricated in linear compatible CMOS (LC²CMOS), an advanced, mixed technology process that combines precision bipolar circuits with low power CMOS logic. The AD7776 is available in both 24-pin DIP and 24-pin SOIC packages; the AD7777 is available in both 28-pin DIP and 28-pin SOIC packages; the AD7778 is available in a 44-pin PQFP package.

***Protected by U.S. Patent No. 4,990,916.**

FUNCTIONAL BLOCK DIAGRAMS

PRELIMINARY TECHNICAL DATA

This information applies to a product under development. Its characteristics and specifications are subject to change without notice. Analog Devices assumes no obligation regarding future manufacture unless otherwise agreed to in writing.

CS	RD	WR	DB0–DB9	Function/Comments
1	X	X	HIGH	Data Port High Impedance
0	1	0	CR Data	Load Control Register (CR) data to Control Register and start a conversion. The contents of the Control Register are described below.
0	0	1	ADC Data	ADC data placed on data bus. Depending upon location CR6 of the Control Register, one or two Read instructions will be required: If CR6 is Low (i.e., single channel conversion selected), a Read instruction returns the conversion data for the channel previously selected by CR0–CR2; If CR6 is High (i.e., simultaneous sampling (double conversion) selected), the first Read instruction returns the conversion data for the channel previously selected by CR0–CR2. A second Read instruction returns the conversion data for the channel previously selected by CR3–CR5.

CONTROL REGISTER CONTENTS

CR0–CR2: Channel Address locations. Determines which channel will be selected and converted for single channel operation. For simultaneous sampling operation, CR0–CR2 holds the address of one of the two channels to be sampled.

CR2	CR1	CR0	Function
0	0	0	Select $A_{IN}1$
0	0	1	Select $A_{IN}2$
0	1	0	Select $A_{IN}3$
0	1	1	Select $A_{IN}4$
1	0	0	Select $A_{IN}5$
1	0	1	Select $A_{IN}6$
1	1	0	Select $A_{IN}7$
1	1	1	Select $A_{IN}8$

CR3–CR5: Channel Address locations. Only applicable for simultaneous sampling when CR3–CR5 holds the address of the second channel to be sampled.

CR5	CR4	CR3	Function
0	0	0	Select $A_{IN}1$
0	0	1	Select $A_{IN}2$
0	1	0	Select $A_{IN}3$
0	1	1	Select $A_{IN}4$
1	0	0	Select $A_{IN}5$
1	0	1	Select $A_{IN}6$
1	1	0	Select $A_{IN}7$
1	1	1	Select $A_{IN}8$

CR6: Determines whether operation is on a single channel or simultaneous sampling on two channels.

CR6	Function
0	Single channel operation. Channel select address is contained in locations CR0–CR2.
1	Two channels simultaneously sampled and sequentially converted. Channel select addresses contained in locations CR0–CR2 and CR3–CR5.

CR7: Determines whether the device is in the Normal Operating mode or in the Calibration mode:

CR7	Function
0	Normal Operating Mode
1	Calibration Mode

In the Calibration mode REFIN is internally connected as an analog input(s).

CR8: Determines whether the device is in the Normal Operating mode or in the Power-Down mode;

CR8	Function
0	Normal Operating Mode
1	Power-Down Mode

CR9: Determines whether $\overline{\text{BUSY/INT}}$ output flag goes Low and remains Low during conversion(s) or else goes Low and remains Low after the conversion(s) is (are) complete.

CR9	$\overline{\text{BUSY/INT}}$ Functionality
0	Output goes Low and remains Low during conversion(s).
1	Output goes Low and remains Low after conversion(s) is (are) complete.

PRELIMINARY TECHNICAL DATA

AD7820

FEATURES

- Fast Conversion Time: 1.36μs max
- Built-In Track-and-Hold Function
- No Missed Codes
- No User Trims Required
- Single +5V Supply
- Ratiometric Operation
- No External Clock
- Extended Temperature Range Operation
- Skinny 20-Pin DIP, SOIC and 20-Terminal Surface Mount Packages

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7820 is a high speed, microprocessor-compatible 8-bit analog-to-digital converter which uses a half-flash conversion technique to achieve a conversion time of 1.36μs. The converter has a 0V to +5V analog input voltage range with a single +5V supply.

The half-flash technique consists of 31 comparators, a most significant 4-bit ADC and a least significant 4-bit ADC. The input to the AD7820 is tracked and held by the input sampling circuitry, eliminating the need for an external sample-and-hold for signals with slew rates less than 100mV/μs.

The part is designed for ease of microprocessor interface with the AD7820 appearing as a memory location or I/O port without the need for external interfacing logic. All digital outputs use latched, three-state output buffer circuitry to allow direct connection to a microprocessor data bus or system input port. A non-three state overflow output is also provided to allow cascading of devices to give higher resolution.

The AD7820 is fabricated in an advanced, all ion-implanted, high speed, Linear Compatible CMOS (LC^2MOS) process and features a low maximum power dissipation of 75mW. It is available in 20-pin DIPs, SOICs and in 20-terminal surface mount packages.

PRODUCT HIGHLIGHTS

1. Fast Conversion Time
   The half-flash conversion technique, coupled with fabrication on Analog Devices' LC^2MOS process, enables very fast conversion times. The maximum conversion time for the WR-RD mode is 1.36μs, with 1.6μs the maximum for the RD mode.
2. Total Unadjusted Error
   The AD7820 features an excellent total unadjusted error figure of less than 1/2LSB over the full operating temperature range. The part is also guaranteed to have no missing codes over the entire temperature range.
3. Built-In Track-and-Hold
   The analog input circuitry uses sampled-data comparators, which by nature have a built-in track-and-hold function. As a result, input signals with slew rates up to 100mV/μs can be converted to 8-bits without external sample-and-hold. This corresponds to a 5V peak-to-peak, 7kHz sine-wave signal.
4. Single Supply
   Operation from a single +5V supply with a positive voltage reference allows operation of the AD7820 in microprocessor systems without any additional power supplies.

AD7820—SPECIFICATIONS

(V_{DD} = +5V; V_{REF} (+) = +5V; V_{REF} (−) = GND = 0V unless otherwise stated). All specifications T_{min} to T_{max} unless otherwise specified. Specifications apply for RD Mode (Pin 7 = 0V)

t_{ID}	50	65	75	ns max	Data Access Time after $\overline{INT}$ (Stand-Alone Operation)

NOTES
[1]Sample tested at 25°C to ensure compliance. All input control signals are specified with tr = tf = 20ns (10% to 90% of +5V) and timed from a voltage level of 1.6V.
[2]C_L = 50pF.
[3]Measured with load circuits of Figure 1 and defined as the time required for an output to cross 0.8V or 2.4V.
[4]Defined as the time required for the data lines to change 0.5V when loaded with the circuits of Figure 2.
Specifications subject to change without notice.

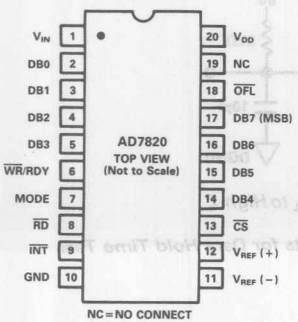
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

CAUTION:
ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.



ORDERING GUIDE

PIN FUNCTION DESCRIPTION

PIN	MNEMONIC	DESCRIPTION
1	V_{IN}	Analog Input. Range: $V_{REF}(-)$ to $V_{REF}(+)$.
2	DB0	Data Output. Three State Output, bit 0 (LSB)
3	DB1	Data Output. Three State Output, bit 1
4	DB2	Data Output. Three State Output, bit 2
5	DB3	Data Output. Three State Output, bit 3
6	$\overline{WR}$/RDY	WRITE control input/READY status output. See Digital Interface section.
7	Mode	Mode Selection Input. It determines whether the device operates in the WR-RD or RD mode. It is internally tied to GND through a 50μA current source. See Digital Interface section.
8	$\overline{RD}$	READ Input. $\overline{RD}$ must be low to access data from the part. See Digital Interface section.
9	$\overline{INT}$	INTERRUPT Output. $\overline{INT}$ going low indicates that the conversion is complete. $\overline{INT}$ returns high on the rising edge of $\overline{RD}$ or $\overline{CS}$. See Digital Interface section.
10	GND	Ground
11	$V_{REF}(-)$	Lower limit of reference span. Range: $GND \leq V_{REF}(-) \leq V_{REF}(+)$
12	$V_{REF}(+)$	Upper limit of reference span. Range: $V_{REF}(-) \leq V_{REF}(+) \leq V_{DD}$
13	$\overline{CS}$	Chip Select Input. $\overline{CS}$, the decoded device address, must be low for $\overline{RD}$ or $\overline{WR}$ to be recognized by the converter.
14	DB4	Data Output. Three State Output, bit 4
15	DB5	Data Output. Three State Output, bit 5
16	DB6	Data Output. Three State Output, bit 6
17	DB7	Data Output. Three State Output, bit 7 (MSB)
18	$\overline{OFL}$	Overflow Output. If the analog input is higher than ($V_{REF}(+) - 1/2$LSB), $\overline{OFL}$ will be low at the end of conversion. It is a non three state output which can be used to cascade 2 or more devices to increase resolution.
19	NC	No connection.
20	V_{DD}	Power supply voltage, +5V

CIRCUIT INFORMATION

BASIC DESCRIPTION

The AD7820 uses a half-flash conversion technique whereby two 4-bit flash A/D converters are used to achieve an 8-bit result. Each 4-bit flash ADC contains 15 comparators which compare the unknown input to a reference ladder to get a 4-bit result. For a full 8-bit reading to be realized, the upper 4-bit flash, the most significant (MS) flash, performs a conversion to provide the 4 most significant data bits. An internal DAC, driven by the 4 MSBs, then recreates an analog approximation of the input voltage. This analog result is subtracted from the input, and the difference is converted by the lower flash ADC, the least significant (LS) flash, to provide the 4 least significant bits of the output data. The MS flash ADC also has one additional comparator to detect input overrange.

OPERATING SEQUENCE

The operating sequence for the AD7820 in the WR-RD mode is shown in Figure 3. A set-up time of 500ns is required prior to the falling edge of $\overline{WR}$. (This 500ns is required between reading data from the AD7820 and starting another conversion). When $\overline{WR}$ is low the input comparators track the analog input signal, V_{IN}. On the rising edge of $\overline{WR}$, the input signal is sampled and the result for the four most significant bits is latched. $\overline{INT}$ goes low approximately 700ns after the rising edge of $\overline{WR}$. This indicates that conversion is complete and the data result is already in the output latch. $\overline{RD}$ going low then accesses the output data. If a faster conversion time is required, the $\overline{RD}$ line can be brought low 600ns after $\overline{WR}$ goes high. This latches the lower 4 bits of data and accesses the output data on DB0–DB7.

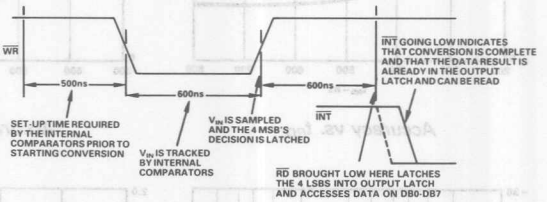

Figure 3. Operating Sequence (WR-RD Mode)

DIGITAL INTERFACE

The AD7820 has two basic interface modes which are determined by the status of the MODE pin. When this pin is low the converter is in the RD mode, with this pin high the AD7820 is set up for the WR-RD mode.

RD Mode

The timing diagram for the RD mode is shown in Figure 4. In the RD mode configuration, conversion is initiated by taking $\overline{RD}$ low. The $\overline{RD}$ line is then kept low until output data appears. It is very useful with microprocessors which can be forced into a WAIT state, with the microprocessor starting a conversion, waiting, and then reading data with a single READ instruction. In this mode, pin 6 of the AD7820 is configured as a status output, RDY. This RDY output can be used to drive the processor READY or WAIT input. It is an open drain output (no internal pull-up device) which goes low after the falling edge of $\overline{CS}$ and goes high impedance at the end of conversion. An $\overline{INT}$ line is also provided which goes low at the completion of conversion. $\overline{INT}$ returns high on the rising edge of $\overline{CS}$ or $\overline{RD}$.

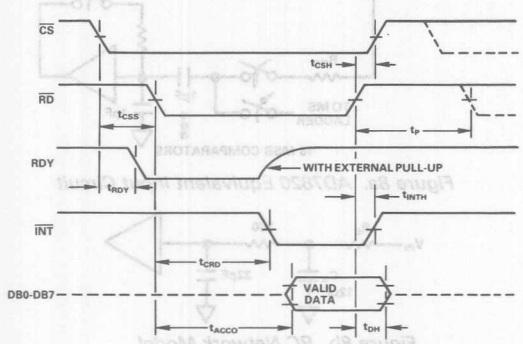

Figure 4. RD Mode

WR-RD Mode

In the WR-RD mode, pin 6 is configured as the WRITE input for the AD7820. With $\overline{CS}$ low, conversion is initiated on the falling edge of $\overline{WR}$. Two options exist for reading data from the converter.

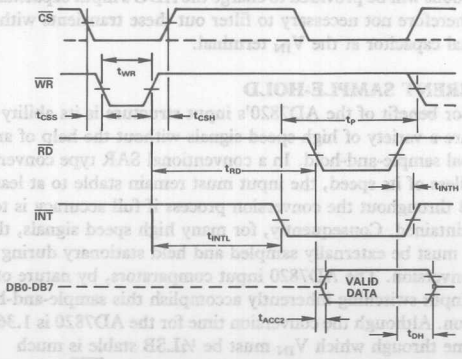

Figure 5a. WR-RD Mode ($t_{RD} > t_{INTL}$)

In the first of these options the processor waits for the $\overline{INT}$ status line to go low before reading the data (see Figure 5a). $\overline{INT}$ typically goes low 700ns after the rising edge of $\overline{WR}$. It indicates that conversion is complete and that the data result is in the output latch. With $\overline{CS}$ low, the data outputs (DB0-DB7) are activated when $\overline{RD}$ goes low. $\overline{INT}$ is reset by the rising edge of $\overline{RD}$ or $\overline{CS}$.

The alternative option can be used to shorten the conversion time. To achieve this, the status of the $\overline{INT}$ line is ignored and $\overline{RD}$ can be brought low 600ns after the rising edge of $\overline{WR}$. In this case $\overline{RD}$ going low transfers the data result into the output latch and activates the data outputs (DB0-DB7). $\overline{INT}$ also goes low on the falling edge of $\overline{RD}$ and is reset on the rising edge of $\overline{RD}$ or $\overline{CS}$. The timing for this interface is shown in Figure 5b.

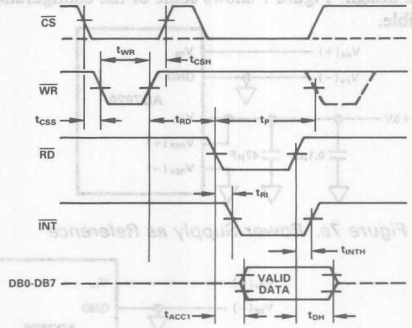

Figure 5b. WR-RD Mode ($t_{RD} < t_{INTL}$)

The AD7820 can also be used in stand-alone operation in the WR-RD mode. $\overline{CS}$ and $\overline{RD}$ are tied low and a conversion is initiated by bringing $\overline{WR}$ low. Output data is valid typically 700ns after the rising edge of $\overline{WR}$. The timing diagram for this mode is shown in Figure 6.

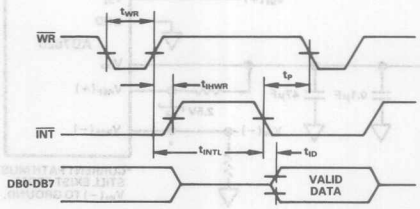

Figure 6. WR-RD Mode Stand-Alone Operation, $\overline{CS} = \overline{RD} = 0$

APPLYING THE AD7820

REFERENCE AND INPUT

The two reference inputs on the AD7820 are fully differential and define the zero to full-scale input range of the A/D converter. As a result, the span of the analog input can easily be varied since this range is equivalent to the voltage difference between $V_{IN}(+)$ and $V_{IN}(-)$. By reducing the reference span, $V_{REF}(+)-V_{REF}(-)$, to less than 5V the sensivity of the converter can be increased (i.e., if $V_{REF} = 2V$ then 1LSB = 7.8mV). The input/reference arrangement also facilitates ratiometric operation.

This reference flexibility also allows the input span to be offset from zero. The voltage at $V_{REF}(-)$ sets the input level which produces a digital output of all zeroes. Therefore, although V_{IN} is not itself differential, it will have nearly differential-input capability in most measurement applications because of the reference design. Figure 7 shows some of the configurations that are possible.

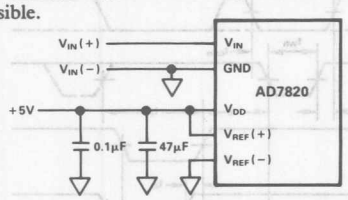

Figure 7a. Power Supply as Reference

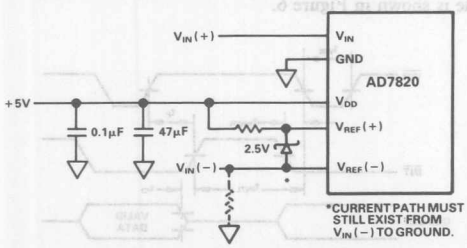

Figure 7c. Input Not Referenced to GND

INPUT CURRENT

Due to the novel conversion techniques employed by the AD7820, the analog input behaves somewhat differently than in conventional devices. The ADC's sampled-data comparators take varying amounts of input current depending on which cycle the conversion is in.

The equivalent input circuit of the AD7820 is shown in Figure 8a. When a conversion starts ($\overline{WR}$ low, WR-RD mode), all input switches close, and V_{IN} is connected to the most significant and least significant comparators. Therefore, V_{IN} is connected to thirty one 1pF input capacitors at the same time.

The input capacitors must charge to the input voltage through the on resistance of the analog switches (about 2kΩ to 5kΩ). In addition, about 12pF of input stray capacitance must be charged. For large source resistances, the analog input can be modelled as an RC network as shown in Figure 8b. As R_S increases, it takes longer for the input capacitance to charge.

In the RD mode, the time for which the input comparators track the analog input is 600ns at the start of conversion. In the WR-RD mode the input comparators track V_{IN} for the duration of the $\overline{WR}$ pulse. Since other factors cause this time to be at least 600ns, input time constants of 100ns can be accommodated without special consideration. Typical total input capacitance values of 45pF allow R_S to be 1.5kΩ without lengthening $\overline{WR}$ to give V_{IN} more time to settle.

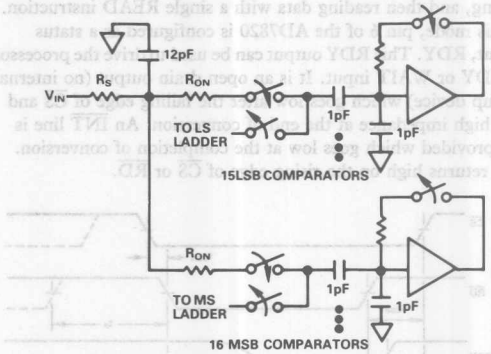

Figure 8a. AD7820 Equivalent Input Circuit

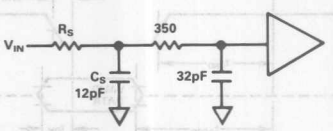

Figure 8b. RC Network Model

INPUT FILTERING

It should be made clear that transients on the analog input signal, caused by charging current flowing into V_{IN} will not normally degrade the ADC's performance. In effect, the AD7820 does not "look" at the input when these transients occur. The comparators' outputs are not latched while $\overline{WR}$ is low, so at least 600ns will be provided to charge the ADC's input capacitance. It is therefore not necessary to filter out these transients with an external capacitor at the V_{IN} terminal.

INHERENT SAMPLE-HOLD

A major benefit of the AD7820's input structure is its ability to measure a variety of high speed signals without the help of an external sample-and-hold. In a conventional SAR type converter, regardless of its speed, the input must remain stable to at least ½LSB throughout the conversion process if full accuracy is to be maintained. Consequently, for many high speed signals, this signal must be externally sampled and held stationary during the conversion. The AD7820 input comparators, by nature of their input switching inherently accomplish this sample-and-hold function. Although the conversion time for the AD7820 is 1.36µs, the time through which V_{IN} must be ½LSB stable is much smaller. The AD7820 "samples" V_{IN} only when $\overline{WR}$ is low. The value of V_{IN} approximately 100ns (internal propogation delay) after the rising edge of $\overline{WR}$ is the measured value. This value is then used in the least significant flash to generate the lower 4-bits of data.

Input signals with slew rates typically below 200mV/μs can be converted without error. However, because of the input time constants, and charge injection through the opened comparator input switches, faster signals may cause errors. Still, the AD7820's loss in accuracy for a given increase in signal slope is far less than what would be witnessed in a conventional successive approximation device. A SAR type converter with a conversion time as fast as 1μs would still not be able to measure a 5V, 1kHz sine wave without the aid of an external sample-and-hold. The AD7820 with no such help, can typically measure 5V, 10kHz waveforms.

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7821 is a high-speed, 8-bit, sampling, analog-to-digital converter that offers improved performance over the popular AD7820. It offers a conversion time of 660 ns (vs. 1.36 µs for the AD7820) and 100 kHz signal bandwidth (vs. 6.4 kHz). The sampling instant is better defined and occurs on the falling edge of $\overline{WR}$ or $\overline{RD}$. The provision of a V_{SS} pin (Pin 19) allows the part to operate from ±5 V supplies and to digitize bipolar input signals. Alternatively, for unipolar inputs, the V_{SS} pin can be grounded and the AD7821 will operate from a single +5 V supply, like the AD7820.

The AD7821 has a built-in track-and-hold function capable of digitizing full-scale signals up to 100 kHz max. It also uses a half-flash conversion technique that eliminates the need to generate a CLK signal for the ADC.

The AD7821 is designed with standard microprocessor control signals ($\overline{CS}$, $\overline{RD}$, $\overline{WR}$, RDY, $\overline{INT}$) and latched, three-state data outputs capable of interfacing to high-speed data buses. An overflow output ($\overline{OFL}$) is also provided for cascading devices to achieve higher resolution.

The AD7821 is fabricated in Linear-Compatible CMOS (LC²MOS), an advanced, mixed technology process combining precision bipolar circuits with low-power CMOS logic. The part features a low power dissipation of 50 mW.

PRODUCT HIGHLIGHTS

1. Fast Conversion Time
   The half-flash conversion technique, coupled with fabrication on Analog Devices' LC²MOS process, enables a very fast conversion time. The conversion time for the WR-RD mode is 660 ns, with 700 ns for the RD mode.
2. Built-In Track-and-Hold
   This allows input signals with slew rates up to 1.6 V/µs to be converted to 8-bits without an external track-and-hold. This corresponds to a 5 V peak-to-peak, 100 kHz sine-wave signal.
3. Total Unadjusted Error
   The AD7821 features an excellent total unadjusted error figure of less than ±1 LSB over the full operating temperature range.
4. Unipolar/Bipolar Input Ranges
   The AD7821 is specified for single supply (+5 V) operation with a unipolar full-scale range of 0 to +5 V, and for dual supply (±5 V) operation with a bipolar input range of ±2.5 V. Typical performance characteristics are given for other input ranges.
5. Dynamic Specifications for DSP Users
   In addition to the traditional ADC specifications, the AD7821 is specified for ac parameters, including signal-to-noise ratio, distortion and slew rate.

AD7821—SPECIFICATIONS

V_{DD} = +5 V ± 5%, GND = 0 V. Unipolar Input Range: V_{SS} = GND, $V_{REF}(+)$ = 5 V, $V_{REF}(-)$ = GND. Bipolar Input Range: V_{SS} = −5 V ± 5%, $V_{REF}(+)$ = 2.5 V, $V_{REF}(-)$ = −2.5 V. These test conditions apply unless otherwise stated. All specifications T_{min} to T_{max} unless otherwise stated. Specifications apply for RD Mode (Pin 7 = 0 V).

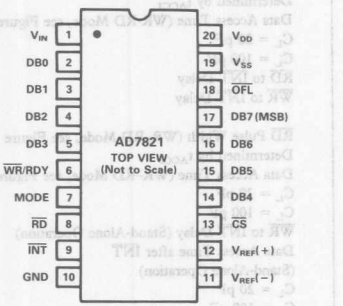
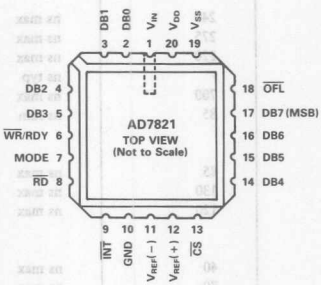
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

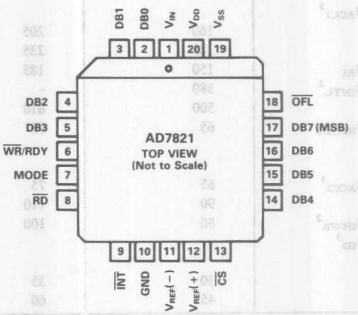


CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.



PIN CONFIGURATIONS



DIP AND SOIC

LCCC

PLCC

TERMINOLOGY

LEAST SIGNIFICANT BIT (LSB)

An ADC with 8-bit resolution can resolve one part in 2^8 (1/256 of full scale). For the AD7821 operating in either the unipolar or bipolar input range with 5 V full scale, one LSB is 19.53 mV.

TOTAL UNADJUSTED ERROR

This is a comprehensive specification which includes relative accuracy, offset error and full-scale error.

SLEW RATE

Slew Rate is the maximum allowable rate of change of input signal such that the digital sample values are not in error.

TOTAL HARMONIC DISTORTION

Total harmonic distortion is the ratio of the square root of the sum of the squares of the rms value of the harmonics to the rms value of the fundamental. For the AD7821, total harmonic distortion (THD) is defined as

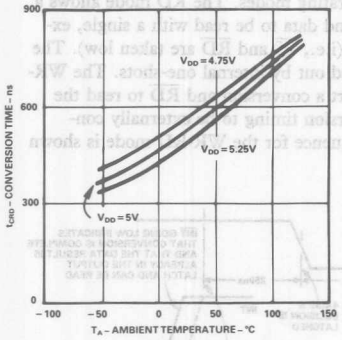
$$20\ log\left[\frac{\sqrt{(V_2^2+V_3^2+V_5^2+V_6^2)}}{V_1}\right] dB$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5, V_6, are the rms amplitudes of the individual harmonics.

INTERMODULATION DISTORTION

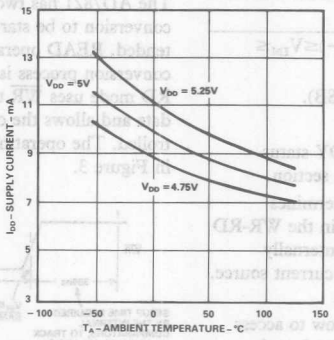
With inputs consisting of sine waves at two frequencies, fa and fb, any active device with nonlinearities will create distortion products, of order (m+n), at sum and difference frequencies of mfa+nfb, where m,n = 0, 1, 2, 3,- - - -. Intermodulation terms are those for which m or n is not equal to zero. For example, the second order terms include (fa + fb) and (fa − fb), and the third order terms include (2fa + fb), (2fa − fb), (fa + 2fb) and (fa − 2fb). For the AD7821 intermodulation distortion is calculated separately for both the second and third order terms.

SIGNAL-TO-NOISE RATIO



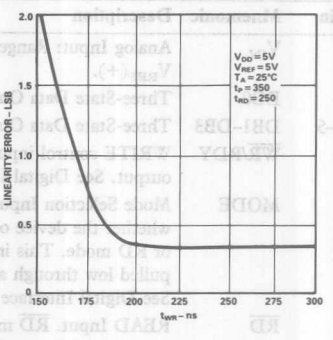
Signal-to-noise ratio (SNR) is measured signal-to-noise at the output of the ADC. The signal is the rms magnitude of the fundamental. Noise is the rms sum of all nonfundamental signals (excluding dc) up to half the sampling frequency. SNR is dependent on the number of quantization levels used in the digitization process. The theoretical SNR for a sine-wave input is given by:

$$SNR = (6.02N + 1.76)\ dB$$



where N is the number of bits in the ADC. Thus, for an ideal 8-bit ADC, SNR = 50 dB.

PEAK HARMONIC OR SPURIOUS NOISE



Peak harmonic or spurious noise is the rms value of the largest nonfundamental frequency (excluding dc) up to half the sampling frequency to the rms value of the fundamental.

PIN FUNCTION DESCRIPTION

Pin	Mnemonic	Description
1	V_{IN}	Analog Input: Range $V_{REF}(-) \le V_{IN} \le V_{REF}(+)$.
2	DB0	Three-State Data Output (LSB).
3–5	DB1–DB3	Three-State Data Outputs.
6	$\overline{WR}$/RDY	WRITE control input/READY status output. See Digital Interface section.
7	MODE	Mode Selection Input. It determines whether the device operates in the WR-RD or RD mode. This input is internally pulled low through a 50 μA current source. See Digital Interface section.
8	$\overline{RD}$	READ Input. $\overline{RD}$ must be low to access data from the part. See Digital Interface section.
9	$\overline{INT}$	INTERRUPT Output. $\overline{INT}$ going low indicates that the conversion is complete. $\overline{INT}$ returns high on the rising edge of $\overline{CS}$ or $\overline{RD}$. See Digital Interface section.
10	GND	Ground.
11	$V_{REF}(-)$	Lower limit of reference span. Range: $V_{SS} \le V_{REF}(-) < V_{REF}(+)$.
12	$V_{REF}(+)$	Upper limit of reference span. Range: $V_{REF}(-) < V_{REF}(+) \le V_{DD}$.
13	$\overline{CS}$	Chip Select Input. The device is selected when this input is low.
14–16	DB4–DB6	Three-State Data Outputs.
17	DB7	Three-State Data Output (MSB).
18	$\overline{OFL}$	Overflow Output. If the analog input is higher than ($V_{REF}(+)$ −1/2 LSB), $\overline{OFL}$ will be low at the end of conversion. It is a non-three-state output which can be used to cascade 2 or more devices to increase resolution.
19	V_{SS}	Negative supply voltage. V_{SS} = 0 V; Unipolar Operation. V_{SS} = −5 V; Bipolar Operation.
20	V_{DD}	Positive supply voltage, +5 V.

CIRCUIT INFORMATION

BASIC DESCRIPTION

The AD7821 uses a half flash conversion technique (see Functional Block Diagram), whereby two 4-bit flash ADCs are used to achieve an 8-bit result. Each 4-bit flash ADC contains 15 comparators, which compare an unknown input voltage to the reference ladder, to achieve a 4-bit result. The MS (most significant) flash ADC converts an unknown analog input voltage (V_{IN}) to provide the 4 MS data bits. An internal DAC, driven by the 4 MS data bits, then recreates an analog approximation of the input voltage. The DAC output voltage is subtracted from the analog input, and the difference is converted by the LS (least significant) ADC to provide the 4 LS data bits. The MS flash ADC also has one additional comparator to detect overrange on the analog input.

OPERATING SEQUENCE

The AD7821 has two operating modes. The RD mode allows a conversion to be started and data to be read with a single, extended, READ operation (i.e., $\overline{CS}$ and $\overline{RD}$ are taken low). The conversion process is timed out by internal one-shots. The WR-RD mode uses $\overline{WR}$ to start a conversion and $\overline{RD}$ to read the data and allows the conversion timing to be externally controlled. The operating sequence for the WR-RD mode is shown in Figure 3.

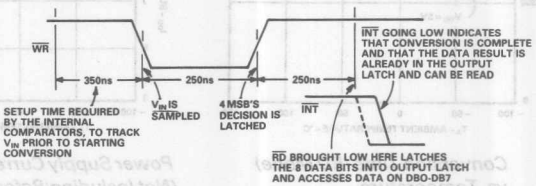

Figure 3. Operating Sequence (WR-RD Mode)

A conversion is initiated and the analog input signal (V_{IN}) sampled on the falling edge of $\overline{WR}$ (falling edge of $\overline{RD}$, RD mode). A setup time (tp, delay time between conversions) of 350 ns is required prior to this falling edge. See Digital Interface section for more details. When $\overline{WR}$ is low, the internal MS (most significant) ADC compares the sampled analog input with the reference ladder to provide the 4 MS data bits. A minimum of 250 ns is required for this comparison. On the rising edge of $\overline{WR}$, the MS data result is latched internally and the LS (least significant) conversion begins, to yield the 4 LS data bits. $\overline{INT}$ goes low typically 380 ns after the rising edge of $\overline{WR}$. This indicates the LS conversion is complete and that both the LS and MS data results are latched into the output buffer. $\overline{RD}$ going low then enables the output data. If a faster conversion time is required, the $\overline{RD}$ line can be brought low 250 ns after $\overline{WR}$ goes high. This latches both the LS and MS data bits and outputs the conversion result on DB0–DB7.

REFERENCE AND INPUT

The V_{REF} (−) and V_{REF} (+) reference inputs on the AD7821 are fully differential and define the zero and full-scale input range of the ADC. The transfer characteristic of the part is defined by the integer value of the following expression:

$$Data\ (LSBs) = 256\left[\frac{V_{IN} - V_{REF}(-)}{V_{REF}(+) - V_{REF}(-)}\right] + 0.5$$

As a result, the analog input (V_{IN}) of the device can easily be set up to provide both unipolar and bipolar operation. The data output code for unipolar and bipolar operation is Natural Binary and Offset Binary, respectively.

The span of the analog input voltage can easily be varied. By reducing the reference span, V_{REF} (+)−V_{REF} (−), to less than 5 V the sensitivity of the converter can be increased (i.e., if V_{REF} = 2 V then 1 LSB = 7.8 mV). The reference flexibility also allows the input span for unipolar operation to be offset from zero (V_{REF} (−)>GND). Additionally, the input/reference arrangement facilitates ratiometric operation.

Figures 4 and 5 show some configurations which are possible. For minimum noise a 47 μF capacitor in parallel with a 0.1 μF capacitor should be connected between the reference inputs and GND.

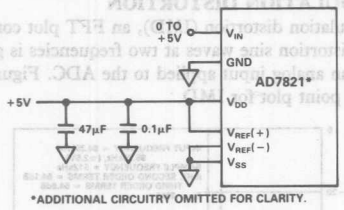

Figure 4. Power Supply as Reference. Unipolar Operation (0 to +5V)

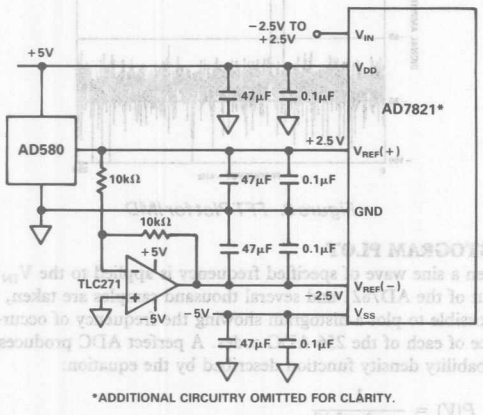

Figure 5. External Reference. Bipolar Operation (−2.5V to +2.5V)

INPUT CURRENT

The analog input of the AD7821 behaves somewhat differently to conventional A/D converters. This is due to the ADC's sampled-data comparators, which take varying amounts of input current depending on the cycle of the converter.

The equivalent input circuit of the AD7821 is shown in Figure 6. When a conversion ends (e.g., falling edge of $\overline{INT}$, WR-RD mode, $t_{RD}>t_{INTL}$) all the input switches are closed and V_{IN} is connected to the comparators of the internal LS and MS ADCs. Therefore, V_{IN} is connected to 31 one - pF input capacitors simultaneously.

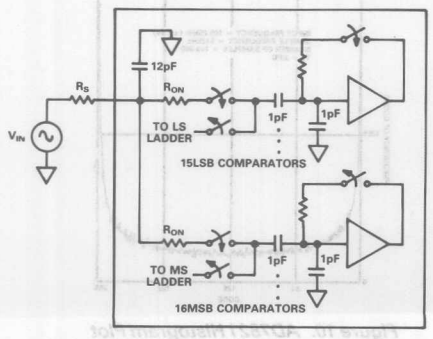

Figure 6. AD7821 Equivalent Input Circuit

The input capacitors must charge to the input voltage through the on resistance of the analog switches (about 2 kΩ to 5 kΩ). In addition, about 12 pF of input stray capacitance must be charged.

The analog input can be modeled as an equivalent RC network as shown in Figure 7. As R_S (source impedance) increases, the input capacitance takes longer to charge.

The comparators track the analog input between conversions. A minimum delay time (t_P) of 350 ns is required between conversions to allow for voltage source settling and comparator tracking time. This allows input time constants of 50 ns without settling time problems. Typical total input capacitance values of 55 pF allow R_S to be 0.9 kΩ without lengthening t_P to give V_{IN} more time to settle.

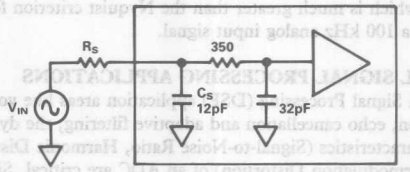

Figure 7. RC Network Model

INPUT TRANSIENTS

Transients on the analog input signal caused by charging current flowing into V_{IN} will not normally degrade the ADC's performance. In effect, the AD7821 does not "look" at the input when these transients occur. The comparators' inputs track V_{IN} and are not sampled until the falling edge of $\overline{WR}$ (WR-RD Mode) or $\overline{RD}$ (RD Mode), so at least 350 ns (t_P) is provided to charge the ADC's input capacitance. It is, therefore, not necessary to filter out these transients with an external capacitor at the V_{IN} terminal.

INHERENT TRACK-AND-HOLD

A major benefit of the AD7821's input structure is its ability to measure a variety of high-speed signals without the help of an external track-and-hold. Any ADC which does not have a built-in track-and-hold, regardless of its speed, requires the analog input to remain stable to at least 1/2 LSB for the duration of the conversion to maintain full accuracy. This requires the use of a track-and-hold whenever the input is a high-speed signal. The AD7821's sampled-data comparators, by nature of their input switching, inherently accomplish this track-and-hold function. Although the conversion time for the AD7821 is 660 ns (WR-RD mode, $t_{WR}+t_{RD}+t_{ACC1}$), the time for which V_{IN} must be stable to 1/2 LSB is much smaller. The AD7821 tracks V_{IN} between conversions only, and its value on the falling edge of $\overline{WR}$ or $\overline{RD}$ in the WR-RD or RD modes, respectively, is the measured value.

SINUSOIDAL INPUTS

The bandwidth of the built-in track-and-hold is 100 kHz max (150 kHz typ, 5 V p-p). This is limited by the analog bandwidth of the comparators and timing skew between the comparator switches. This means that the analog input frequency can be up to 100 kHz without the aid of an external track-and-hold. The Nyquist criterion requires that the sampling rate be at least twice the input frequency (i.e., ≥2×100 kHz). This requires an ideal antialiasing filter with an infinite roll-off. To ease the

problem of antialiasing filter design, the sampling rate is usually set much greater than the Nyquist criterion. The maximum sampling rate (f_{max}) for the AD7821 in the WR-RD mode, ($t_{RD} < t_{INTL}$) can be calculated as follows:

$$f_{max} = \frac{1}{t_{WR} + t_{RD} + t_{RI} + t_P}$$

$$f_{max} = \frac{1}{0.25E-6 + 0.25E-6 + 0.15E-6 + 0.35E-6}$$

t_{WR} = *Write Pulse Width*

t_{RD} = *Delay Time between* $\overline{WR}$ *and* $\overline{RD}$ *Pulses*

t_{RI} = $\overline{RD}$ *to* $\overline{INT}$ *Delay*

t_P = *Delay Time between Conversions*

This permits a maximum sampling rate for the AD7821 of 1 MHz, which is much greater than the Nyquist criterion for sampling a 100 kHz analog input signal.

DIGITAL SIGNAL PROCESSING APPLICATIONS

In Digital Signal Processing (DSP) application areas like voice recognition, echo cancellation and adaptive filtering, the dynamic characteristics (Signal-to-Noise Ratio, Harmonic Distortion, Intermodulation Distortion) of an ADC are critical. Since the AD7821 is a very fast ADC with a built-in track-and-hold function, it is specified dynamically as well as with standard dc specifications (Total Unadjusted Error, etc.).

SIGNAL-TO-NOISE RATIO AND DISTORTION

The dynamic performance of the AD7821 is evaluated by applying a very low distortion sine-wave signal to the analog input (V_{IN}) which is then sampled at a 512 kHz sampling rate. A Fast Fourier Transform (FFT) plot is then generated from which Signal-to-Noise Ratio (SNR) and harmonic distortion data are obtained.

Figure 8 shows a 2048 point FFT plot of the AD7821 with an input signal of 100.25 kHz. The SNR is 49.1 dB. It should be noted that the harmonics are taken into account when calculating the SNR. The theoretical relationship between SNR and resolution (N) is expressed by the following equation:

$$SNR = (6.02N + 1.76)\ dB \quad \ldots\ldots\ldots\ldots\ldots\ldots (1)$$

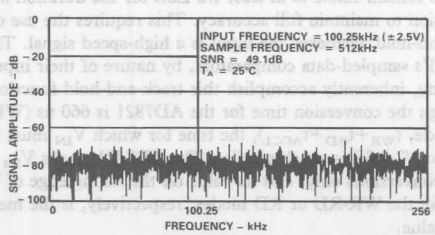

Figure 8. AD7821 FFT Plot

EFFECTIVE NUMBER OF BITS

By working backwards from Equation (1) it is possible to get a measure of ADC performance expressed in effective number of bits (N). A plot of the effective number of bits versus input frequency is given in the Typical Performance Characteristics section. The effective number of bits typically falls between 7.7 and 7.9, corresponding to SNR figures of 48.1 and 49.7 dB.

INTERMODULATION DISTORTION

For intermodulation distortion (IMD), an FFT plot consisting of very low distortion sine waves at two frequencies is generated by sampling an analog input applied to the ADC. Figure 9 shows a 2048 point plot for IMD.

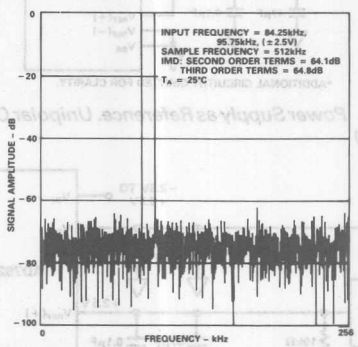

Figure 9. FFT Plot for IMD

HISTOGRAM PLOT

When a sine wave of specified frequency is applied to the V_{IN} input of the AD7821 and several thousand samples are taken, it is possible to plot a histogram showing the frequency of occurrence of each of the 256 ADC codes. A perfect ADC produces a probability density function described by the equation:

$$P(V) = \frac{1}{\pi(A^2 - V^2)^{1/2}}$$

where A is the peak amplitude of the sine wave and P(V) is the probability of occurrence at a voltage V.

If a particular step is wider than the ideal 1 LSB width, then the code associated with that step will accumulate more counts than for the code for an ideal step. Likewise, a step narrower than the ideal width will have fewer counts. Missing codes are easily seen because a missing code means zero counts for a particular code. The absence of large spikes in the plot indicates small differential nonlinearity.

Figure 10 shows a histogram plot for the AD7821, which corresponds very well with the ideal shape. The plot indicates very small differential nonlinearity and no missing codes for an input frequency of 100.25 kHz.

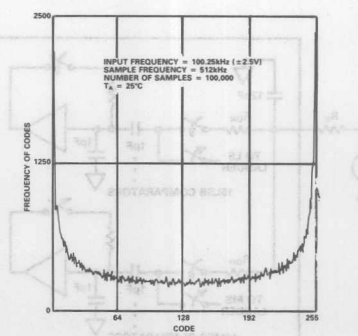

Figure 10. AD7821 Histogram Plot

In digital signal processing applications, where the AD7821 is used to sample ac signals, it is essential that the signal sampling occurs at exactly equal intervals. This minimizes errors due to sampling uncertainty or jitter. A precise timer or clock source, to start the ADC conversion process, is the best method of generating equidistant sampling intervals.

The two modes of operation given in the data sheet are suitable for DSP applications because the sampling instant of the AD7821 is well defined. V_{IN} is sampled on the falling edge of $\overline{WR}$ or $\overline{RD}$ in the WR-RD or RD modes, respectively.

DIGITAL INTERFACE

The AD7821 has two basic interface modes which are determined by the status of the MODE pin. When this pin is low, the converter is in the RD mode; with this pin high, the AD7821 is set up for the WR-RD mode.

The RD mode is designed for microprocessors that can be driven into a WAIT state. A READ operation (i.e., $\overline{CS}$ and $\overline{RD}$ are taken low) starts a conversion and data is read when the conversion is complete. The WR-RD mode does not require microprocessor WAIT states. A WRITE operation (i.e., $\overline{CS}$ and $\overline{WR}$ are taken low) initiates a conversion, and a READ operation reads the result when the conversion is complete.

RD Mode (MODE = 0)

The timing diagram for the RD mode is shown in Figure 11. This mode is intended for use with microprocessors which have a WAIT state facility, whereby a READ instruction cycle can be extended to accommodate slow memory devices. A conversion is started by taking $\overline{CS}$ and $\overline{RD}$ low (READ operation). Both $\overline{CS}$ and $\overline{RD}$ are then kept low until output data appears.

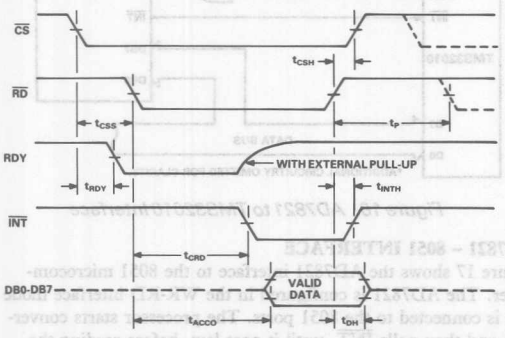

Figure 11. RD Mode

In this mode, Pin 6 of the AD7821 is configured as a status output, RDY. This RDY output can be used to drive the processor READY or WAIT input. It is an open drain output (no internal pull-up device) which goes low after the falling edge of $\overline{CS}$ and goes high impedance at the end of conversion. An $\overline{INT}$ line is also provided which goes low when a conversion is complete. $\overline{INT}$ returns high on the rising edge of $\overline{CS}$ or $\overline{RD}$.

WR-RD Mode (MODE = 1)

In the WR-RD mode, Pin 6 is configured as a WRITE ($\overline{WR}$) input for the AD7821. With $\overline{CS}$ low, conversion is initiated on the falling edge of $\overline{WR}$. Two options exist for reading data from the converter.

In the first of these options the processor waits for the $\overline{INT}$ status line to go low before reading the data (see Figure 12a).

$\overline{INT}$ typically goes low within 380 ns after the rising edge of $\overline{WR}$. It indicates that conversion is complete and that the data result is in the output latch. With $\overline{CS}$ low, the data outputs (DB0–DB7) are activated when $\overline{RD}$ goes low. $\overline{INT}$ is reset by the rising edge of $\overline{RD}$ or $\overline{CS}$.

The alternative option can be used to shorten the conversion time. This is a method for bypassing the internal time-out circuit. The $\overline{INT}$ line is ignored and $\overline{RD}$ can be brought low

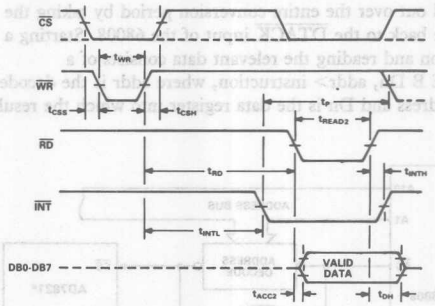

Figure 12a. WR-RD Mode ($t_{RD} > t_{INTL}$)

250 ns after the rising edge of $\overline{WR}$. In this case $\overline{RD}$ going low transfers the data result into the output latch and activates the data output (DB0–DB7). $\overline{INT}$ is driven low on the falling edge of $\overline{RD}$ and is reset on the rising edge of $\overline{RD}$ or $\overline{CS}$. The timing for this interface is shown in Figure 12b.

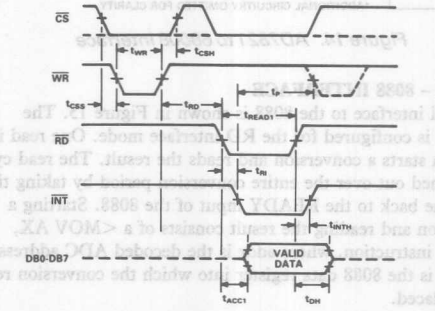

Figure 12b. WR-RD Mode ($t_{RD} < t_{INTL}$)

The AD7821 can also be used in stand-alone operation in the WR-RD mode. $\overline{CS}$ and $\overline{RD}$ are tied low, and a conversion is initiated by bringing $\overline{WR}$ low. Output data is valid 530 ns ($t_{INTL} + t_{ID}$) after the rising edge of $\overline{WR}$. The timing diagram for this mode is shown in Figure 13.

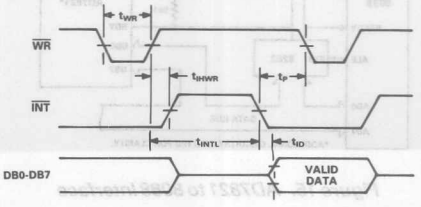

Figure 13. WR-RD Mode Stand-Alone Operation, $\overline{CS} = \overline{RD} = 0$

MICROPROCESSOR INTERFACING

The AD7821 is designed for easy interfacing to microprocessors as a memory mapped peripheral or an I/O device. This reduces to a minimum the amount of external logic required for interfacing.

AD7821 – 68008 INTERFACE

Figure 14 shows an AD7821 interface to the 68008 microprocessor. The ADC is configured for the RD interface mode. This means that one read instruction starts a conversion and reads the result when the conversion is completed. The read cycle is stretched out over the entire conversion period by taking the $\overline{INT}$ line back to the $\overline{DTACK}$ input of the 68008. Starting a conversion and reading the relevant data consists of a <MOVE B Dn, addr> instruction, where addr is the decoded ADC address and Dn is the data register into which the result is placed.

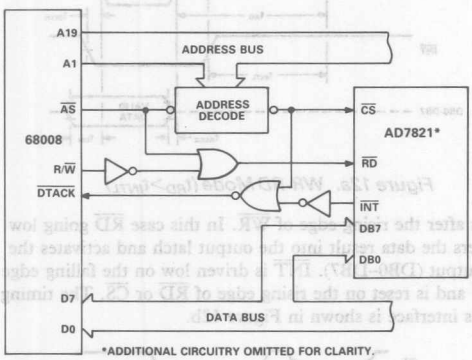

Figure 14. AD7821 to 68008 Interface

AD7821 – 8088 INTERFACE

A typical interface to the 8088 is shown in Figure 15. The AD7821 is configured for the RD interface mode. One read instruction starts a conversion and reads the result. The read cycle is stretched out over the entire conversion period by taking the RDY line back to the READY input of the 8088. Starting a conversion and reading the result consists of a <MOV AX, (addr)> instruction, where addr is the decoded ADC address and AX is the 8088 data register into which the conversion result is placed.

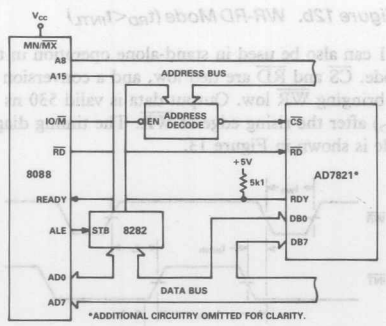

Figure 15. AD7821 to 8088 Interface

AD7821 – TMS32010 INTERFACE

A typical interface to the TMS32010 is shown in Figure 16. The AD7821 is mapped at a port address and the interface is designed for the maximum TMS32010 clock frequency of 20 MHz. In this case, the AD7821 is configured in the WR-RD interface mode. This means that a write instruction starts a conversion and a read instruction reads the result when the conversion is completed. A precise timer or clock source is used to start a conversion in applications requiring equidistant sampling intervals. The scheme used, whereby the AD7821 generates an interrupt to the TMS32010, is limited in that it does not allow the AD7821 to be sampled at its maximum rate. This is because the time between samples has to be long enough to allow the TMS32010 to service its interrupt and read data from the AD7821. Constant interruption of the TMS32010 by the AD7821, every time the ADC completes a conversion, is not a very efficient use of the processor time. To overcome these problems, some buffer memory or FIFO could be placed between the AD7821 and the TMS32010. The $\overline{INT}$ line of the AD7821 could be used to trigger a pulse which drives its $\overline{CS}$ and $\overline{RD}$ lines and places the AD7821 data into a FIFO or buffer memory. The microprocessor can then read a batch of data from the FIFO or buffer memory at some convenient time. Reading data from the AD7821, after an $\overline{INT}$ has been received, consists of <IN A, PA> instruction (PA is the decoded ADC address).

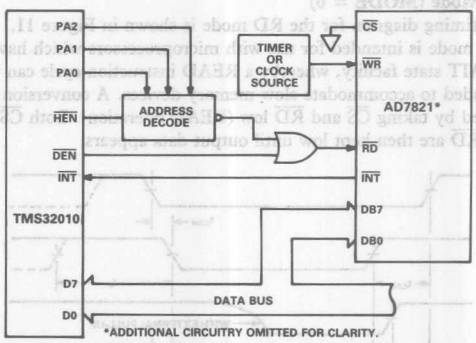

Figure 16. AD7821 to TMS32010 Interface

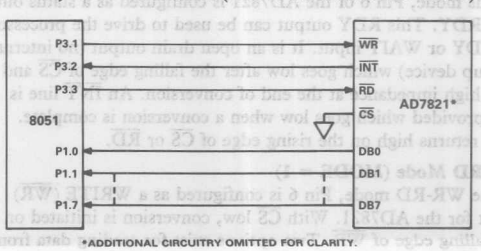
AD7821 – 8051 INTERFACE

Figure 17 shows the AD7821 interface to the 8051 microcomputer. The AD7821 is configured in the WR-RD interface mode and is connected to the 8051 ports. The processor starts conversion and then polls $\overline{INT}$, until it goes low, before reading the conversion result. Data is read from the AD7821 by using the <MOV A, 90H> instruction (90H is the address for Port 1).



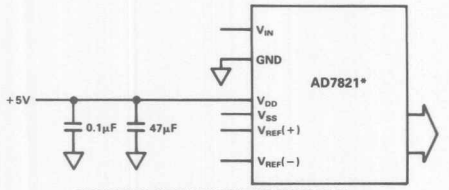


Figure 17. AD7821 to 8051 Interface

APPLYING THE AD7821

The AD7821 is specified for a unipolar input range of 0 to +5 V and a bipolar input range of −2.5 V to +2.5 V. The $V_{REF}(-)$ and $V_{REF}(+)$ voltages required for these input ranges are outlined below. See the Typical Performance Characteristics section for operation with unspecified input voltage ranges.

UNIPOLAR OPERATION

Figure 18 gives the configuration and reference voltages required for 0 to +5 V operation. The nominal transfer characteristic for this input range is shown in Figure 19. The output code is Natural Binary with 1 LSB = (5/256) V = 19.5 mV.

*ADDITIONAL CIRCUITRY OMITTED FOR CLARITY.

$V_{REF}(+)$	$V_{REF}(-)$	V_{SS}	V_{IN}	RANGE
+5V	GND	GND	UNIPOLAR	0 to +5V
+2.5V	−2.5V	−5V	BIPOLAR	−2.5V to +2.5V

Figure 18. AD7821 Unipolar/Bipolar Operation

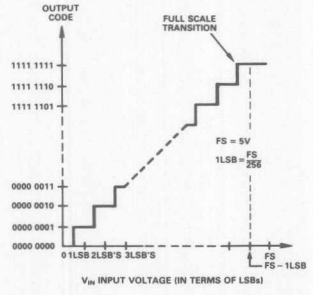

Figure 19. Nominal Transfer Characteristic for Unipolar (0 to +5 V) Operation

BIPOLAR OPERATION

Figure 18 gives the configuration and reference voltages required for −2.5 V to +2.5 V operation. The nominal transfer characteristic for this input range is shown in Figure 20. The output code is Offset Binary with 1 LSB = ([+2.5 − (−2.5)]/256)V = 19.5 mV.

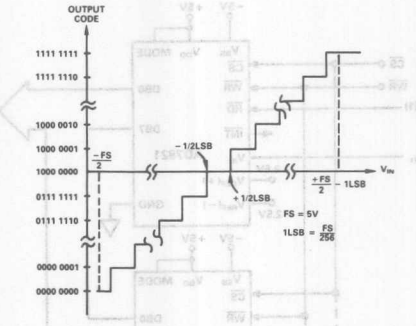

Figure 20. Nominal Transfer Characteristic for Bipolar (−2.5 V to +2.5 V) Operation

16-CHANNEL TELECOM A/D CONVERTER

The fast sampling rate (1 MHz) and bipolar operation of the AD7821 makes it useful in Telecom applications for sampling a number of input channels using a multiplexer. Figure 21 shows a circuit for such an application.

The maximum signal frequency required for acceptable quality in Telecom applications is 3 kHz. The circuit given in Figure 21 permits each of the 16-input channels to be sampled at a rate of 16 kHz maximum. The sampling rate takes account of such multiplexer parameters as t_{ON}, settling time etc. The circuit also eases the problem of the antialiasing filter design by sampling at a rate much greater than that required by the Nyquist criterion.

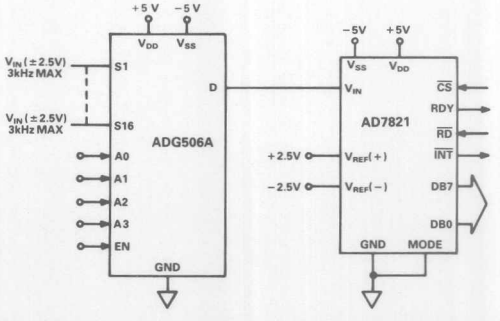

Figure 21. 16-Channel Telecom A/D Converter System

SIMULTANEOUS SAMPLING A/D CONVERTERS

The AD7821's inherent track-and-hold and well-defined sampling instant makes it useful, in such applications as sonar, where a number of input channels are required to be sampled simultaneously. Figure 22 shows a circuit for such an application.

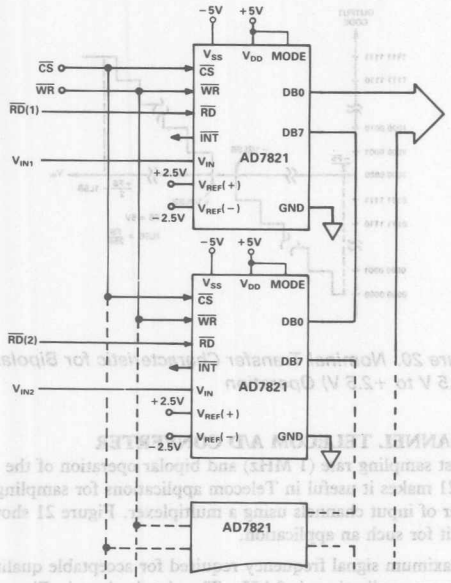

Figure 22. Simultaneous Sampling A/D Converters

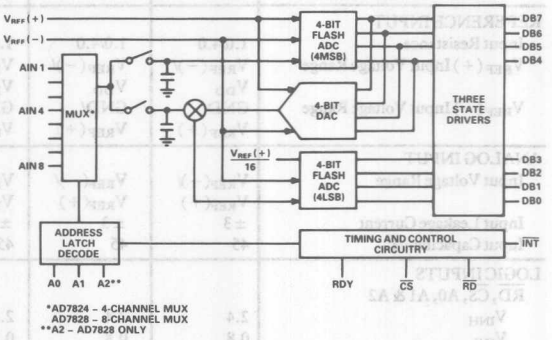
The actual sampling instant, which is the instant at which V_{IN} is measured, occurs approximately 50 ns after the falling edge of $\overline{WR}$ or $\overline{RD}$ in the WR-RD or RD modes, respectively, due to internal logic delays. However, the internal logic delay and, therefore, the sampling instant can vary from device to device, but is typically within ±5 ns. This means that a maximum common input sine wave of ±2.5 V at 32 kHz, applied to any number of AD7821s in the circuit of Figure 22, will yield a maximum difference between the converter outputs of typically ±1/4 LSB.



LC²MOS High Speed 4- & 8-Channel 8-Bit ADCs

AD7824/AD7828

FEATURES

4- or 8-Analog Input Channels
Built-In Track/Hold Function
10kHz Signal Handling on Each Channel
Fast Microprocessor Interface
Single +5V Supply
Low Power: 50mW
Fast Conversion Rate, 2.5μs/Channel
Tight Error Specification: 1/2LSB

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7824 and AD7828 are high-speed, multichannel, 8-bit ADCs with a choice of 4 (AD7824) or 8 (AD7828) multiplexed analog inputs. A half-flash conversion technique gives a fast conversion rate of 2.5μs per channel and the parts have a built-in track/hold function capable of digitizing full-scale signals of 10kHz (157mV/μs slew rate) on all channels. The AD7824 and AD7828 operate from a single +5V supply and have an analog input range of 0 to +5V, using an external +5V reference.

Microprocessor interfacing of the parts is simple, using standard Chip Select ($\overline{CS}$) and Read ($\overline{RD}$) signals to intitiate the conversion and read the data from the three-state data outputs. The half-flash conversion technique means that there is no need to generate a clock signal for the ADC. The AD7824 and AD7828 can be interfaced easily to most popular microprocessors.

The AD7824 and AD7828 are fabricated in an advanced, all ion-implanted, Linear-Compatible CMOS process (LC²MOS) and have low power dissipation of 40mW (typ). The AD7824 is available in a 0.3″ wide, 24-pin "skinny" DIP, while the AD7828 is available in a 0.6″ wide, 28-pin DIP and in 28-terminal surface mount packages.

PRODUCT HIGHLIGHTS

1. 4- or 8-channel input multiplexer gives cost-effective space-saving multichannel ADC system.
2. Fast conversion rate of 2.5μs/channel features a per channel sampling frequency of 100kHz for the AD7824 or 50kHz for the AD7828.
3. Built-in track-hold function allows handling of 4- or 8-channels up to 10kHz bandwidth (157mV/μs slew rate).
4. Tight total unadjusted error spec and channel-to-channel matching eliminate the need for user trims.
5. Single +5V supply simplifies system power requirements.
6. Fast, easy-to-use digital interface allows connection to most popular microprocessors with minimal external components. No clock signal is required for the ADC.

AD7824/AD7828—SPECIFICATIONS

(V_{DD} = +5V, $V_{REF}(+)$ = +5V, $V_{REF}(-)$ = GND = 0V unless otherwise stated. All specifications T_{min} to T_{max} unless otherwise specified. Specifications apply for Mode 0.)

NOTES
[1]Sample tested at 25°C to ensure compliance. All input control signals are specified with tr = tf = 20ns (10% to 90% of +5V) and timed from a voltage level of 1.6V.
[2]C_L = 50pF.
[3]Measured with load circuits of Figure 1 and defined as the time required for an output to cross 0.8V or 2.4V.
[4]Defined as the time required for the data lines to change 0.5V when loaded with the circuits of Figure 2.
Specifications subject to change without notice.

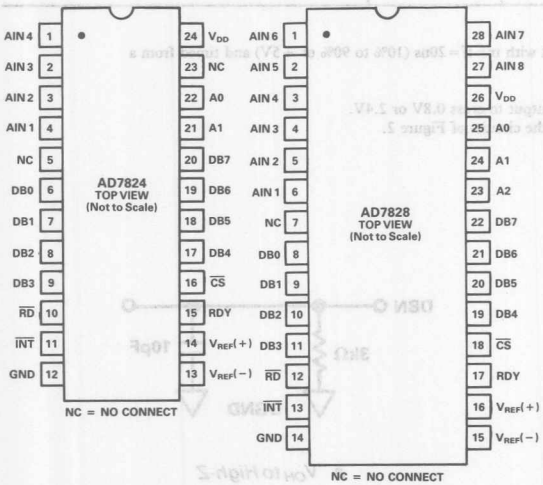
*Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.



CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

OPERATIONAL DIAGRAM

The AD7824 is a 4-channel 8-bit A/D converter and the AD7828 is an 8-channel 8-bit A/D converter. Operational diagrams for both of these devices are shown in Figures 3 and 4. The addition of just a +5V reference allows the devices to perform the analog-to-digital function.

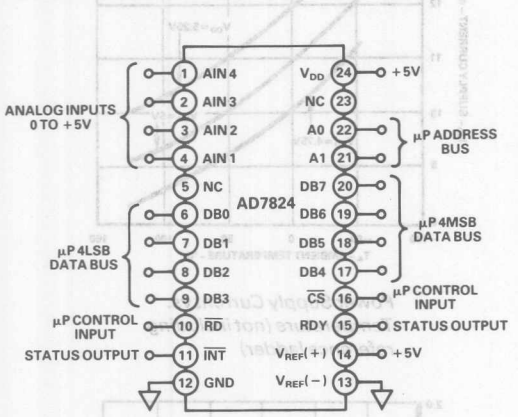

Figure 3. AD7824 Operational Diagram

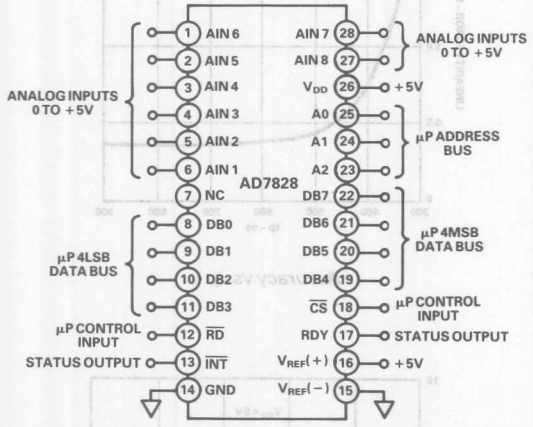

Figure 4. AD7828 Operational Diagram

CIRCUIT INFORMATION

BASIC DESCRIPTION

The AD7824/AD7828 uses a half-flash conversion technique whereby two 4-bit flash A/D converters are used to achieve an 8-bit result. Each 4-bit flash ADC contains 15 comparators which compare the unknown input to a reference ladder to get a 4-bit result. For a full 8-bit reading to be realized, the upper 4-bit flash, the most significant (MS) flash, performs a conversion to provide the 4 most significant data bits. An internal DAC, driven by the 4MSBs, then recreates an analog approximation of the input voltage. This analog result is subtracted from the input, and the difference is converted by the lower flash ADC, the least significant (LS) flash, to provide the 4 least significant bits of the output data.

APPLYING THE AD7824/AD7828

REFERENCE AND INPUT

The two reference inputs on the AD7824/AD7828 are fully differential and define the zero to full-scale input range of the A/D converter. As a result, the span of the analog input voltage for all channels can easily be varied. By reducing the reference span, $V_{REF}(+) - V_{REF}(-)$, to less than 5V the sensitivity of the converter can be increased (e.g., if V_{REF} = 2V then 1LSB = 7.8mV). The input/reference arrangement also facilitates ratiometric operation.

This reference flexibility also allows the input channel voltage span to be offset from zero. The voltage at $V_{REF}(-)$ sets the input level for all channels which produces a digital output of all zeroes. Therefore, although the analog inputs are not themselves differential, they have nearly differential-input capability in most measurement applications because of the reference design. Figures 5 to 7 show some of the configurations that are possible.

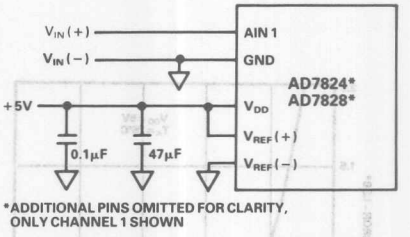

Figure 5. Power Supply as Reference

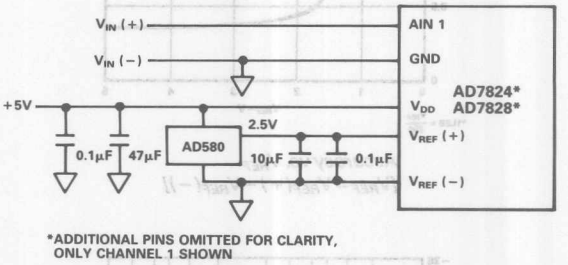

Figure 6. External Reference Using the AD580, Full-Scale Input is 2.5V

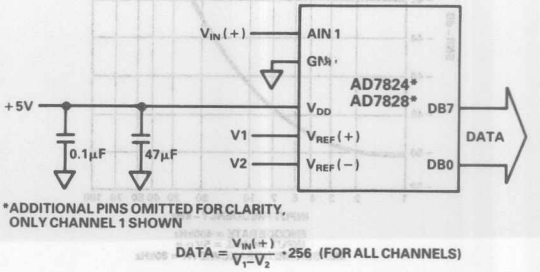

Figure 7. Input Not Referenced to GND

INPUT CURRENT

Due to the novel conversion techniques employed by the AD7824/AD7828, the analog input behaves somewhat differently than in conventional devices. The ADC's sampled-data comparators take varying amounts of input current depending on which cycle the conversion is in.

The equivalent input circuit of the AD7824/AD7828 is shown in Figure 8. When a conversion starts ($\overline{CS}$ and $\overline{RD}$ going low), all input switches close, and the selected input channel is connected to the most significant and least significant comparators. Therefore, the analog input is connected to thirty-one 1pF input capacitors at the same time.

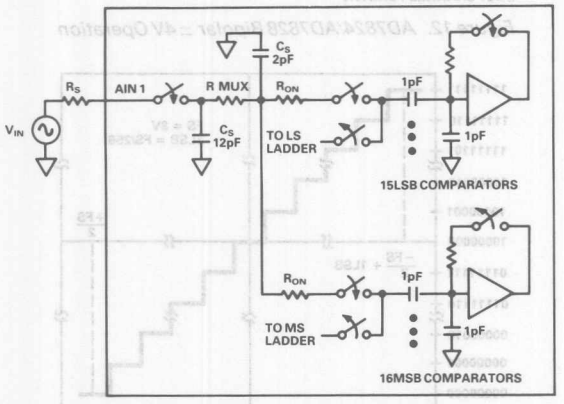

Figure 8. AD7824/AD7828 Equivalent Input Circuit

The input capacitors must charge to the input voltage through the on resistance of the analog switches (about 3k to 6k). In addition, about 14pF of input stray capacitance must be charged. The analog input for any channel can be modelled as an RC network as shown in Figure 9. As R_S increases, it takes longer for the input capacitance to charge.

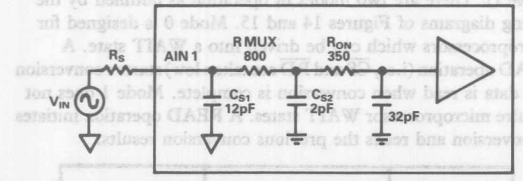

Figure 9. RC Network Model

The time for which the input comparators track the analog input is approximately 1μs at the start of conversion. Because of input transients on the analog inputs, it is recommended that a source impedence of not greater than 100 ohms be connected to the analog inputs. The output impedence of an op-amp is equal to the open loop output impedence divided by the loop gain at the frequency of interest. It is important that the amplifier driving the AD7824/AD7828 analog inputs have sufficient loop gain at the input signal frequency as to make the output impedance low.

Suitable op-amps for driving the AD7824/AD7828 are the AD544 or AD644.

INHERENT SAMPLE-HOLD

A major benefit of the AD7824's and AD7828's analog input structure is its ability to measure a variety of high-speed signals without the help of an external sample-and-hold. In a conventional SAR type converter, regardless of its speed, the input must remain stable to at least 1/2LSB throughout the conversion process if rated accuracy is to be maintained. Consequently, for many high-speed signals, this signal must be externally sampled and held stationary during the conversion. The AD7824/AD7828 input comparators, by nature of their input switching inherently accomplish this sample-and-hold function. Although the conversion time for AD7824/ AD7828 is 2μs, the time for which any selected analog input must be 1/2LSB stable is much smaller. The AD7824/AD7828 tracks the selected input channel for approximately 1μs after conversion start. The value of the analog input at that instant (1μs from conversion start) is the measured value. This value is then used in the least significant flash to generate the lower 4-bits of data.

SINUSOIDAL INPUTS

The AD7824/AD7828 can measure input signals with slew rates as high as 157mV/μs to the rated specifications. This means that the analog input frequency can be up to 10kHz without the aid of an external sample and hold. Furthermore, the AD7828 can measure eight 10kHz signals without a sample and hold. The Nyquist criterion requires that the sampling rate be twice the input frequency (i.e., 2 × 10kHz). This requires an ideal anti-aliasing filter with an infinite roll-off. To ease the problem of anti-aliasing filter design, the sampling rate is usually much greater than the Nyquist criterion. The maximum sampling rate (F_{max}) for the AD7824/AD7828 can be calculated as follows:

$$F_{max} = \frac{1}{t_{CRD} + t_p}$$

$$F_{max} = \frac{1}{2E-6+0.5E-6} = 400kHz$$

t_{CRD} = AD7824/AD7828 Conversion Time
t_P = Minimum Delay Between Conversion

This permits a maximum sampling rate of 50kHz for each of the 8 channels when using the AD7828 and 100kHz for each of the 4 channels when using the AD7824.

UNIPOLAR OPERATION

The analog input range for any channel of the AD7824/AD7828 is 0 to 5V as shown in the unipolar operational diagram of Figure 10. Figure 11 shows the designed code transitions which occur midway between successive integer LSB values (i.e., 1/2LSB, 3/2LSB, 5/2LSB, FS-3/2LSBs). The output code is Natural Binary with 1LSB = FS/256 = (5/256)V = 19.5mV.

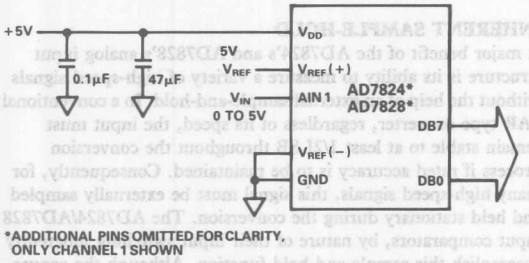

Figure 10. AD7824/AD7828 Unipolar 0 to 5V Operation

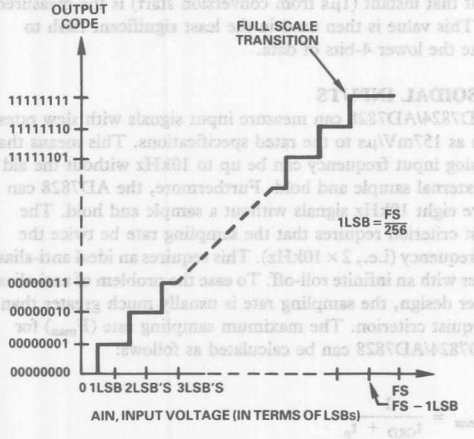

Figure 11. Ideal Input/Output Transfer Characteristic for Unipolar 0 to +5V Operation

BIPOLAR OPERATION

The circuit of Figure 12 is designed for bipolar operation. An AD544 op-amp conditions the signal input (V_{IN}) so that only positive voltages appear at AIN 1. The closed loop transfer function of the op-amp for the resistor values shown is given below:

$$AIN\ 1 = (2.5 - 0.625\ V_{IN})\ Volts$$

The analog input range is ±4V and the LSB size is 31.25mV. The output code is complementary offset binary. The ideal input/output characteristic is shown in Figure 13.

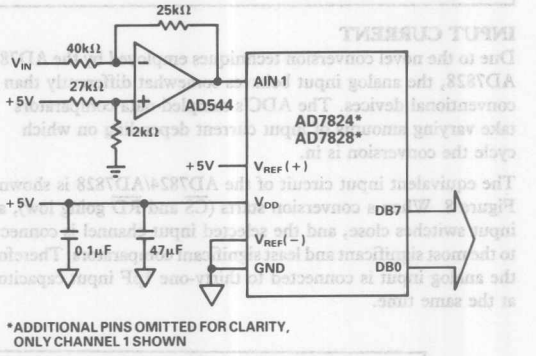

Figure 12. AD7824/AD7828 Bipolar ±4V Operation

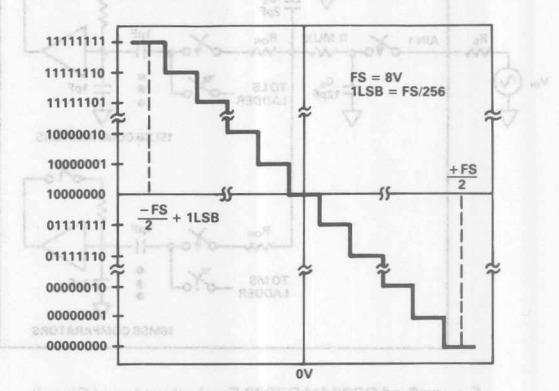

Figure 13. Ideal Input/Output Transfer Characteristic for ±4V Operation

TIMING AND CONTROL

The AD7824/AD7828 has two digital inputs for timing and control. These are Chip Select ($\overline{CS}$) and Read ($\overline{RD}$). A READ operation brings $\overline{CS}$ and $\overline{RD}$ low which starts a conversion on the channel selected by the multiplexer address inputs (see Table I). There are two modes of operation as outlined by the timing diagrams of Figures 14 and 15. Mode 0 is designed for microprocessors which can be driven into a WAIT state. A READ operation (i.e., $\overline{CS}$ and $\overline{RD}$ are taken low) starts a conversion and data is read when conversion is complete. Mode 1 does not require microprocessor WAIT states. A READ operation initiates a conversion and reads the previous conversion results.

AD7824		AD7828			CHANNEL
A1	A0	A2	A1	A0	
0	0	0	0	0	AIN 1
0	1	0	0	1	AIN 2
1	0	0	1	0	AIN 3
1	1	0	1	1	AIN 4
		1	0	0	AIN 5
		1	0	1	AIN 6
		1	1	0	AIN 7
		1	1	1	AIN 8

Table I. Truth Table for Input Channel Selection

MODE 0

Figure 14 shows the timing diagram for Mode 0 operation. This mode can only be used for microprocessors which have a WAIT state facility, whereby a READ instruction cycle can be extended to accommodate slow memory devices. A READ operation brings $\overline{CS}$ and $\overline{RD}$ low which starts a conversion. The analog multiplexer address inputs must remain valid while $\overline{CS}$ and $\overline{RD}$ are low. The data bus (DB7-DB0) remains in the three-state condition until conversion is complete. There are two converter status outputs on the AD7824/AD7828, interrupt ($\overline{INT}$) and ready (RDY) which can be used to drive the microprocessor READY/WAIT input. The RDY is an open drain output (no internal pull-up device) which goes low on the falling edge of $\overline{CS}$ and goes high impedance at the end of conversion, when the 8-bit conversion result appears on the data outputs. If the RDY status is not required, then the external pull-up resistor can be omitted and the RDY output tied to GND. The $\overline{INT}$ goes low when conversion is complete and returns high on the rising edge of $\overline{CS}$ or $\overline{RD}$.

MODE 1

Mode 1 operation is designed for applications where the microprocessor is not forced into a WAIT state. A READ operation takes $\overline{CS}$ and $\overline{RD}$ low which triggers a conversion (see Figure 15). The multiplexer address inputs are latched on the rising edge of $\overline{RD}$. Data from the previous conversion is read from the three-state data outputs (DB7-DB0). This data may be disregarded if not required. Note, the RDY output (open drain output) does not provide any status information in this mode and must be connected to GND. At the end of conversion $\overline{INT}$ goes low. A second READ operation is required to access the new conversion result. This READ operation latches a new address into the multiplexer inputs and starts another conversion. $\overline{INT}$ returns high at the end of the second READ operation, when $\overline{CS}$ or $\overline{RD}$ returns high. A delay of 2.5μs must be allowed between READ operations.

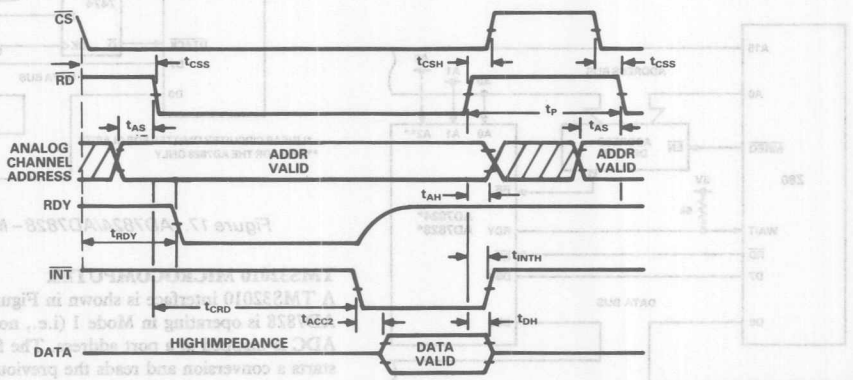

Figure 14. Mode 0 Timing Diagram

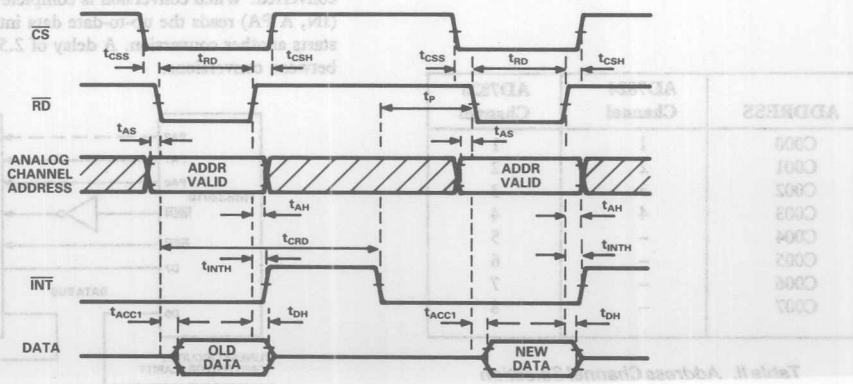

Figure 15. Mode 1 Timing Diagram

AD7824/AD7828 read operations are controlled by CS, RD and the channel address inputs. These signals are common to all memory peripheral devices.

Z80 MICROPROCESSOR

Figure 16 shows a typical AD7824/AD7828 – Z80 interface. The AD7824/AD7828 is operating in Mode 0. Assume the ADC is assigned a memory block starting at address C000. The following LOAD instruction to any of the addresses listed in Table II will start a conversion of the selected channel and read the conversion result.

LD B, (C000)

At the beginning of the instruction cycle when the ADC address is selected, RDY asserts the WAIT input, so that the Z80 is forced into a WAIT state. At the end of conversion RDY returns high and the conversion result is placed in the B register of the microprocessor.

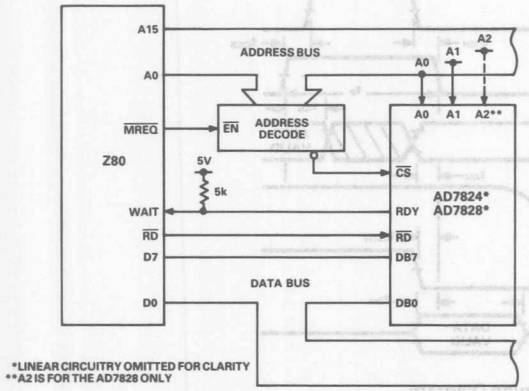

Figure 16. AD7824/AD7828 – Z80 Interface

ADDRESS	AD7824 Channel	AD7828 Channel
C000	1	1
C001	2	2
C002	3	3
C003	4	4
C004	–	5
C005	–	6
C006	–	7
C007	–	8

Table II. Address Channel Selection

block starting at address C000. A MOVE instruction to any of the addresses in Table II starts a conversion and reads the conversion result.

MOVE·B $C000,D0

Once conversion has begun, the MC68000 inserts WAIT states, until INT goes low asserting DTACK at the end of conversion. The microprocessor then places the conversion results in the D0 register.

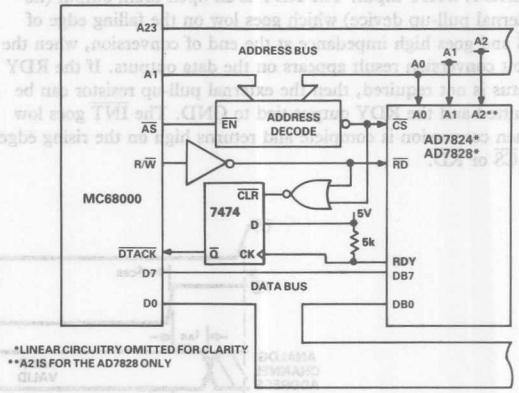

Figure 17. AD7824/AD7828 – MC68000 Interface

TMS32010 MICROCOMPUTER

A TMS32010 interface is shown in Figure 18. The AD7824/AD7828 is operating in Mode 1 (i.e., no μP WAIT states). The ADC is mapped at a port address. The following I/O instruction starts a conversion and reads the previous conversion result into the accumulator.

IN, A PA (PA = PORT ADDRESS)

The port address (000 to 111) selects the analog channel to be converted. When conversion is complete a second I/O instruction (IN, A PA) reads the up-to-date data into the accumulator and starts another conversion. A delay of 2.5μs must be allowed between conversions.

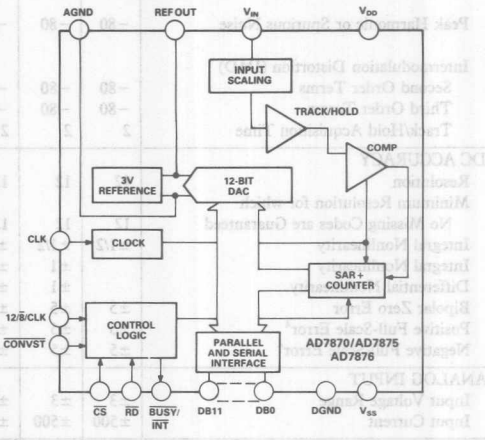
ANALOG DEVICES

LC²MOS Complete, 12-Bit, 100 kHz, Sampling ADCs

AD7870/AD7875/AD7876

FEATURES

Complete Monolithic 12-Bit ADC with:
- 2 μs Track/Hold Amplifier
- 8 μs A/D Converter
- On-Chip Reference
- Laser-Trimmed Clock
- Parallel, Byte and Serial Digital Interface



72 dB SNR at 10 kHz Input Frequency (AD7870, AD7875)

57 ns Data Access Time

Low Power −60 mW typ

Variety of Input Ranges:
- ±3 V for AD7870
- 0 to +5 V for AD7875
- ±10 V for AD7876

FUNCTIONAL BLOCK DIAGRAM

GENERAL DESCRIPTION

The AD7870/AD7875/AD7876 is a fast, complete, 12-bit A/D converter. It consists of a track/hold amplifier, 8 μs successive-approximation ADC, 3 V buried Zener reference and versatile interface logic. The ADC features a self-contained internal clock which is laser trimmed to guarantee accurate control of conversion time. No external clock timing components are required; the on-chip clock may be overridden by an external clock if required.

The parts offer a choice of three data output formats: a single, parallel, 12-bit word; two 8-bit bytes, or serial data. Fast bus access times and standard control inputs ensure easy interfacing to modern microprocessors and digital signal processors.

All parts operate from ±5 V power supplies. The AD7870 and AD7876 accept input signal ranges of ±3 V and ±10 V, respectively, while the AD7875 accepts a unipolar 0 to +5 V input range. The parts can convert full power signals up to 50 kHz.

The AD7870/AD7875/AD7876 feature dc accuracy specifications such as linearity, full-scale and offset error. In addition, the AD7870 and AD7875 are fully specified for dynamic performance parameters including distortion and signal-to-noise ratio.

The parts are fabricated in Analog Devices' Linear Compatible CMOS (LC²MOS) process, a mixed technology process that combines precision bipolar circuits with low-power CMOS logic. The parts are available in a 24-pin, 0.3 inch-wide, plastic or hermetic dual-in-line package (DIP). The AD7870 and AD7875 are available in a 28-pin plastic leaded chip carrier (PLCC), while the AD7876 is available and in a 24-pin small outline (SOIC) package.

PRODUCT HIGHLIGHTS

1. Complete 12-Bit ADC on a Chip.
   The AD7870/AD7875/AD7876 provides all the functions necessary for analog-to-digital conversion and combines a 12-bit ADC with internal clock, track/hold amplifier and reference on a single chip.
2. Dynamic Specifications for DSP Users.
   The AD7870 and AD7875 are fully specified and tested for ac parameters, including signal-to-noise ratio, harmonic distortion and intermodulation distortion.
3. Fast Microprocessor Interface.
   Data access times of 57 ns make the parts compatible with modern 8- and 16-bit microprocessors and digital signal processors. Key digital timing parameters are tested and guaranteed over the full operating temperature range.

NOTES

[1]Temperature ranges are as follows: AD7875: K, L Versions, 0 to +70°C; B, C Versions, −40°C to +85°C; T Version, −55°C to +125°C. AD7876: B, C Versions, −40°C to +85°C; T Version, −55°C to +125°C.

[2]Includes internal reference error and is calculated after unipolar offset error (AD7875) or bipolar zero error (AD7876) has been adjusted out. Full-scale error refers to both positive and negative full-scale error for the AD7876.

[3]Dynamic performance parameters are not tested on the AD7876 but these are typically the same as for the AD7875.

[4]SNR calculation includes distortion and noise components.

[5]Sample tested @ +25°C to ensure compliance.

Specifications subject to change without notice.

t_{20}	0	0	ns min	HBEN to $\overline{CS}$ Hold Time

NOTES

[1]Timing specifications in **bold print** are 100% production tested. All other times are sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

[2]Serial timing is measured with a 4.7 kΩ pull-up resistor on SDATA and $\overline{SSTRB}$ and a 2 kΩ pull-up on SCLK. The capacitance on all three outputs is 35 pF.

[3]t_6 is measured with the load circuits of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.

[4]t_7 is defined as the time required for the data lines to change 0.5 V when loaded with the circuits of Figure 2.

[5]SCLK mark/space ratio (measured from a voltage level of 1.6 V) is 40/60 to 60/40.

[6]SDATA will drive higher capacitive loads but this will add to t_{12} since it increases the external RC time constant (4.7 kΩ||C_L) and hence the time to reach 2.4 V. Specifications subject to change without notice.

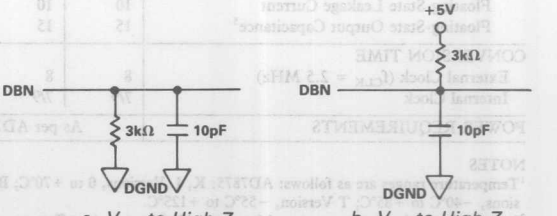

Figure 2. Load Circuits for Output Float Delay

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are inserted.

DIP Pin No.	Pin Mnemonic	Function
1	$\overline{RD}$	Read. Active low logic input. This input is used in conjunction with $\overline{CS}$ low to enable the data outputs.
2	$\overline{BUSY/INT}$	Busy/Interrupt, Active low logic output indicating converter status. See timing diagrams.
3	CLK	Clock input. An external TTL-compatible clock may be applied to this input pin. Alternatively, tying this pin to V_{SS} enables the internal laser-trimmed clock oscillator.
4	DB11/HBEN	Data Bit 11 (MSB)/High Byte Enable. The function of this pin is dependent on the state of the 12/$\overline{8}$/CLK input (see below). When 12-bit parallel data is selected, this pin provides the DB11 output. When byte data is selected, this pin becomes the HBEN logic input. HBEN is used for 8-bit bus interfacing. When HBEN is low, DB7/LOW to DB0/DB8 become DB7 to DB0. With HBEN high, DB7/LOW to DB0/DB8 are used for the upper byte of data (see Table I).
5	DB10/$\overline{SSTRB}$	Data Bit 10/Serial Strobe. When 12-bit parallel data is selected, this pin provides the DB10 output. $\overline{SSTRB}$ is an active low open-drain output that provides a strobe or framing pulse for serial data. An external 4.7 kΩ pull-up resistor is required on $\overline{SSTRB}$.
6	DB9/SCLK	Data Bit 9/Serial Clock. When 12-bit parallel data is selected, this pin provides the DB9 output. SCLK is the gated serial clock output derived from the internal or external ADC clock. If the 12/$\overline{8}$/CLK input is at −5 V, then SCLK runs continuously. If 12/$\overline{8}$/CLK is at 0 V, then SCLK is gated off after serial transmission is complete. SCLK is an open-drain output and requires an external 2 kΩ pull-up resistor.
7	DB8/SDATA	Data Bit 8/Serial Data. When 12-bit parallel data is selected, this pin provides the DB8 output. SDATA is an open-drain serial data output which is used with SCLK and $\overline{SSTRB}$ for serial data transfer. Serial data is valid on the falling edge of SCLK while $\overline{SSTRB}$ is low. An external 4.7 kΩ pull-up resistor is required on SDATA.
8–11	DB7/LOW–DB4/LOW	Three-state data outputs which are controlled by $\overline{CS}$ and $\overline{RD}$. Their function depends on the 12/$\overline{8}$/CLK and HBEN inputs. With 12/$\overline{8}$/CLK high, they are always DB7-DB4. With 12/$\overline{8}$/CLK low or −5 V, their function is controlled by HBEN (see Table I).
12	DGND	Digital Ground. Ground reference for digital circuitry.
13–16	DB3/DB11–DB0/DB8	Three-state data outputs which are controlled by $\overline{CS}$ and $\overline{RD}$. Their function depends on the 12/$\overline{8}$/CLK and HBEN inputs. With/12/$\overline{8}$/CLK high, they are always DB3-DB0. With 12/$\overline{8}$/CLK low or −5 V, their function is controlled by HBEN (see Table I).

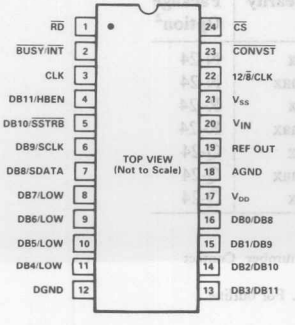

Table I. Output Data for Byte Interfacing

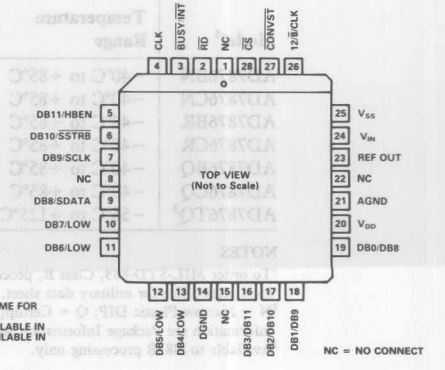
HBEN	DB7/LOW	DB6/LOW	DB5/LOW	DB4/LOW	DB3/DB11	DB2/DB10	DB1/DB9	DB0/DB8
HIGH	LOW	LOW	LOW	LOW	DB11 (MSB)	DB10	DB9	DB8
LOW	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0 (LSB)



17	V_{DD}	Positive Supply, +5 V ±5%.
18	AGND	Analog Ground. Ground reference for track/hold, reference and DAC.
19	REF OUT	Voltage Reference Output. The internal 3 V reference is provided at this pin. The external load capability is 500 μA.
20	V_{IN}	Analog Input. The analog input range is ±3 V for the AD7870, ±10 V for the AD7876 and 0 to +5 V for the AD7875.
21	V_{SS}	Negative Supply, −5 V ±5%.
22	12/$\overline{8}$/CLK	Three Function Input. Defines the data format and serial clock format. With this pin at +5 V, the output data format is 12-bit parallel only. With this pin at 0 V, either byte or serial data is available and SCLK is not continuous. With this pin at −5 V, byte or serial data is again available but SCLK is now continuous.
23	$\overline{CONVST}$	Convert Start. A low to high transition on this input puts the track/hold into its hold mode and starts conversion. This input is asynchronous to the CLK input.
24	$\overline{CS}$	Chip Select. Active low logic input. The device is selected when this input is active. With $\overline{CONVST}$ tied low, a new conversion is initiated when $\overline{CS}$ goes low.

PIN CONFIGURATIONS[1]

DIP and SOIC[2]

PLCC[2]

NC = NO CONNECT

[1]PIN CONFIGURATIONS ARE THE SAME FOR THE AD7870, AD7875 AND AD7876.
[2]THE AD7870 AND AD7875 ARE AVAILABLE IN DIP AND PLCC; THE AD7876 IS AVAILABLE IN DIP AND SOIC.

CONVERTER DETAILS

The AD7870/AD7875/AD7876 is a complete 12-bit A/D converter, requiring no external components apart from power supply decoupling capacitors. It is comprised of a 12-bit successive approximation ADC based on a fast settling voltage-output DAC, a high speed comparator and SAR, a track/hold amplifier, a 3 V buried Zener reference, a clock oscillator and control logic.

INTERNAL REFERENCE

The AD7870/AD7875/AD7876 has an on-chip temperature compensated buried Zener reference which is factory trimmed to 3 V ±10 mV. Internally it provides both the DAC reference and the dc bias required for bipolar operation (AD7870 and AD7876). The reference output is available (REF OUT) and is capable of providing up to 500 μA to an external load.

The maximum recommended capacitance on REF OUT for normal operation is 50 pF. If the reference is required for use external to the ADC, it should be decoupled with a 200 Ω resistor in series with a parallel combination of a 10 μF tantalum capacitor and a 0.1 μF ceramic capacitor. These decoupling components are required to remove voltage spikes caused by the ADC's internal operation.

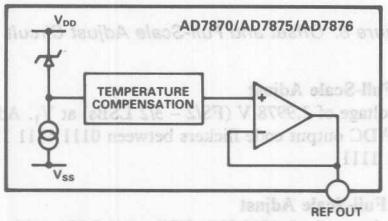


Figure 3. Reference Circuit

The reference output voltage is 3 V. For applications using the AD7875 or AD7876, a 5 V or 10 V reference may be required. Figure 4 shows how to scale the 3 V REF OUT voltage to provide either a 5 V or 10 V external reference.

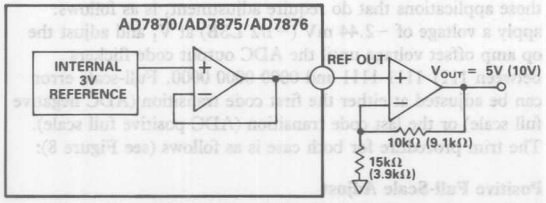

Figure 4. Generating a 5 V or 10 V Reference

TRACK-AND-HOLD AMPLIFIER

The track-and-hold amplifier on the analog input of the AD7870/AD7875/AD7876 allows the ADC to accurately convert input frequencies to 12-bit accuracy. The input bandwidth of the track/hold amplifier is much greater than the Nyquist rate of the ADC even when the ADC is operated at its maximum throughput rate. The 0.1 dB cutoff frequency occurs typically at 500 kHz. The track/hold amplifier acquires an input signal to 12-bit accuracy in less than 2 μs. The overall throughput rate is equal to the conversion time plus the track/hold amplifier acquisition time. For a 2.5 MHz input clock the throughput rate is 10 μs max.

The operation of the track/hold is essentially transparent to the user. The track/hold amplifier goes from its tracking mode to its hold mode at the start of conversion. If the $\overline{\text{CONVST}}$ input is used to start conversion then the track to hold transition occurs on the rising edge of $\overline{\text{CONVST}}$. If $\overline{\text{CS}}$ starts conversion, this transition occurs on the falling edge of $\overline{\text{CS}}$.

2

ANALOG INPUT

The three parts differ from each other in the analog input voltage range which they can handle. The AD7870 accepts ±3 V input signals, the AD7876 accepts a ±10 V input range, while the input range for the AD7875 is 0 to +5 V.

Figure 5a shows the AD7870 analog input. The analog input range is ±3 V into an input resistance of typically 15 kΩ. The designed code transitions occur midway between successive integer LSB values (i.e., 1/2 LSB, 3/2 LSBs, 5/2 LSBs . . . FS−3/2 LSBs). The output code is 2s complement binary with 1 LSB = FS/4096 =6 V/4096 =1.46 mV. The ideal input/output transfer function is shown in Figure 6.

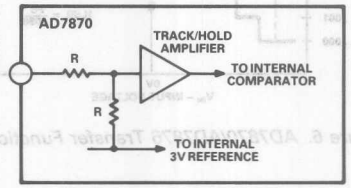

Figure 5a. AD7870 Analog Input

The AD7876 analog input structure is shown in Figure 5b. The analog input range is ±10 V into an input resistance of typically 33 kΩ. As before, the designed code transitions occur midway between successive integer LSB values. The output code is 2s complement with 1 LSB = FS/4096 = 20V/4096 = 4.88 mV. The ideal input/output transfer function is shown in Figure 6.

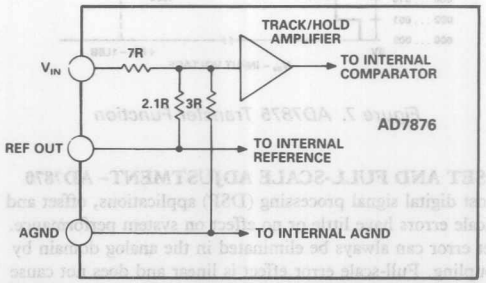

Figure 5b. AD7876 Analog Input

Figure 5c shows the analog input for the AD7875. The input range is 0 to +5 V into an input resistance of typically 25 kΩ. Once again, the designed code transitions occur midway between successive integer LSB values. The output code is

straight binary with 1 LSB = FS/4096 = 5V/4096 = 1.22 mV. The ideal input/output transfer function is shown in Figure 7.

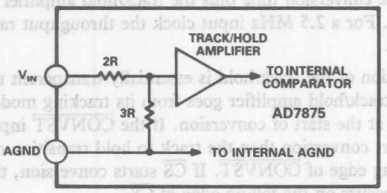

Figure 5c. AD7875 Analog Input

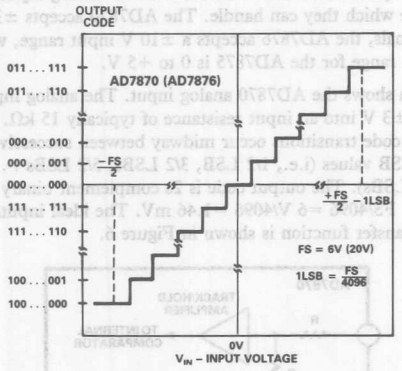

Figure 6. AD7870/AD7876 Transfer Function

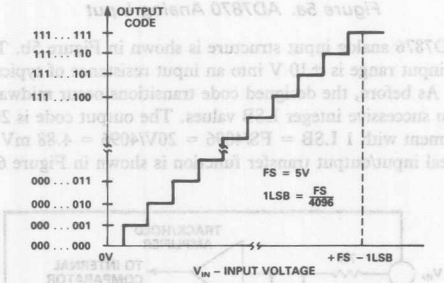

Figure 7. AD7875 Transfer Function

OFFSET AND FULL-SCALE ADJUSTMENT– AD7870

In most digital signal processing (DSP) applications, offset and full-scale errors have little or no effect on system performance. Offset error can always be eliminated in the analog domain by ac coupling. Full-scale error effect is linear and does not cause problems as long as the input signal is within the full dynamic range of the ADC. Some applications will require that the input signal span the full analog input dynamic range. In such applications, offset and full-scale error will have to be adjusted to zero.

Where adjustment is required, offset error must be adjusted before full-scale error. This is achieved by trimming the offset of the op amp driving the analog input of the AD7870 while the input voltage is 1/2 LSB below ground. The trim procedure is as follows: apply a voltage of −0.73 mV(−1/2 LSB) at V_1 in Figure 8 and adjust the op amp offset voltage until the ADC output code flickers between 1111 1111 1111 and 0000 0000 0000. Gain error can be adjusted at either the first code transition (ADC negative full-scale) or the last code transition (ADC positive full scale). The trim procedures for both cases are as follows (see Figure 8).

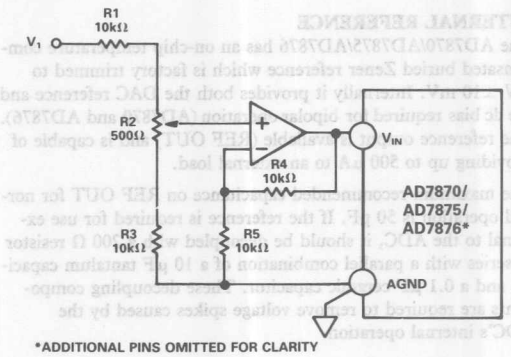

Figure 8. Offset and Full-Scale Adjust Circuit

Positive Full-Scale Adjust
Apply a voltage of 2.9978 V (FS/2 – 3/2 LSBs) at V_1. Adjust R2 until the ADC output code flickers between 0111 1111 1110 and 0111 1111 1111.

Negative Full-Scale Adjust
Apply a voltage of −2.9993 V (−FS/2 +1/2 LSB) at V_1 and adjust R2 until the ADC output code flickers between 1000 0000 0000 and 1000 0000 0001.

OFFSET AND FULL-SCALE ADJUSTMENT – AD7876

The offset and full-scale adjustment for the AD7876 is similar to that just outlined for the AD7870. The trim procedure, for those applications that do require adjustment, is as follows: apply a voltage of −2.44 mV (−1/2 LSB) at V_1 and adjust the op amp offset voltage until the ADC output code flickers between 1111 1111 1111 and 0000 0000 0000. Full-scale error can be adjusted at either the first code transition (ADC negative full scale) or the last code transition (ADC positive full scale). The trim procedure for both case is as follows (see Figure 8):

Positive Full-Scale Adjust
Apply a voltage of 9.9927 V (FS/2 − 3/2 LSBs) at V_1. Adjust R2 until the ADC output code flickers between 0111 1111 1110 and 0111 1111 1111.

Negative Full-Scale Adjust
Apply a voltage of −9.9976 V (FS/2 + 1/2 LSB) at V_1 and adjust R2 until the ADC output code flickers between 1000 0000 0000 and 1000 0000 0001.

OFFSET AND FULL-SCALE ADJUSTMENT – AD7875

Similar to the AD7870, most of the DSP applications in which the AD7875 will be used will not require offset and full-scale adjustment. For applications that do require adjustment, offset error must be adjusted before full-scale (gain) error. This is achieved by applying an input voltage of 0.61 mV (1/2 LSB) to V_1 in Figure 8 and adjusting the op amp offset voltage until the ADC output code flickers between 0000 0000 0000 and 0000 0000 0001. For full-scale adjustment, apply an input voltage of 4.9982 V (FS − 3/2 LSBs) to V_1 and adjust R2 until the ADC output code flickers between 1111 1111 1110 and 1111 1111 1111.

TIMING AND CONTROL

The AD7870/AD7875/AD7876 is capable of two basic operating modes. In the first mode (Mode 1), the $\overline{\text{CONVST}}$ line is used to start conversion and drive the track/hold into its hold mode. At the end of conversion the track/hold returns to its tracking mode. It is intended principally for digital signal processing and other applications where precise sampling in time is required. In these applications, it is important that the signal sampling occurs at exactly equal intervals to minimize errors due to sampling uncertainty or jitter. For these cases, the $\overline{\text{CONVST}}$ line is driven by a timer or some precise clock source.

The second mode is achieved by hard-wiring the $\overline{\text{CONVST}}$ line low. This mode (Mode 2) is intended for use in systems where the microprocessor has total control of the ADC, both initiating the conversion and reading the data. $\overline{\text{CS}}$ starts conversion and the microprocessor will normally be driven into a WAIT state for the duration of conversion by $\overline{\text{BUSY/INT}}$.

DATA OUTPUT FORMATS

In addition to the two operating modes, the AD7870/AD7875/AD7876 also offers a choice of three data output formats, one serial and two parallel. The parallel data formats are a single, 12-bit parallel word for 16-bit data buses and a two-byte format for 8-bit data buses. The data format is controlled by the 12/$\overline{8}$/CLK input. A logic high on this pin selects the 12-bit parallel output format only. A logic low or −5 V applied to this pin allows the user access to either serial or byte formatted data. Three of the pins previously assigned to the four MSBs in parallel form are now used for serial communications while the fourth pin becomes a control input for the byte-formatted data. The three possible data output formats can be selected in either of the modes of operation.

Parallel Output Format

The two parallel formats available on the part are a 12-bit wide data word and a two-byte data word. In the first, all 12 bits of data are available at the same time on DB11 (MSB) through DB0 (LSB). In the second, two reads are required to access the data. When this data format is selected, the DB11/HBEN pin assumes the HBEN function. HBEN selects which byte of data is to be read from the ADC. When HBEN is low, the lower 8 bits of data are placed on the data bus during a read operation; with HBEN high, the upper 4 bits of the 12-bit word are placed on the data bus. These 4 bits are right justified and thereby occupy the lower nibble of data while the upper nibble contains four zeros.

Serial Output Format

Serial data is available on the AD7870/AD7875/AD7876 when the 12/$\overline{8}$/CLK input is at 0 V or −5 V and in this case the DB10/$\overline{\text{SSTRB}}$, DB9/SCLK and DB8/SDATA pins assume their serial functions. Serial data is available during conversion with a word length of 16 bits; four leading zeros, followed by the 12-bit conversion result starting with the MSB. The data is synchronized to the serial clock output (SCLK) and is framed by the serial strobe ($\overline{\text{SSTRB}}$). Data is clocked out on a low to high transition of the serial clock and is valid on the falling edge of this clock while the $\overline{\text{SSTRB}}$ output is low. $\overline{\text{SSTRB}}$ goes low within three clock cycles after $\overline{\text{CONVST}}$, and the first serial data bit (which is the first leading zero) is valid on the first falling edge of SCLK. All three serial lines are open-drain outputs and require external pull-up resistors.

The serial clock out is derived from the ADC clock source which may be internal or external. Normally, SCLK is required during the serial transmission only. In these cases, it can be shut down at the end of conversion to allow multiple ADCs to share a common serial bus. However, some serial systems (e.g., TMS32020) require a serial clock which runs continuously. Both options are available on the AD7870/AD7875/AD7876 using the 12/$\overline{8}$/CLK input. With this input at −5 V, the serial clock (SCLK) runs continuously; when 12/$\overline{8}$/CLK is at 0 V, SCLK is turned off at the end of transmission.

MODE 1 INTERFACE

Conversion is initiated by a low going pulse on the $\overline{\text{CONVST}}$ input. The rising edge of this $\overline{\text{CONVST}}$ pulse starts conversion and drives the track/hold amplifier into its hold mode. Conversion will not be initiated if the $\overline{\text{CS}}$ is low. The $\overline{\text{BUSY/INT}}$ status output assumes its $\overline{\text{INT}}$ function in this mode. $\overline{\text{INT}}$ is normally high and goes low at the end of conversion. This $\overline{\text{INT}}$ line can be used to interrupt the microprocessor. A read operation to the ADC accesses the data and the $\overline{\text{INT}}$ line is reset high on the falling edge of $\overline{\text{CS}}$ and $\overline{\text{RD}}$. The $\overline{\text{CONVST}}$ input must be high when $\overline{\text{CS}}$ and $\overline{\text{RD}}$ are brought low for the ADC to operate correctly in this mode. The $\overline{\text{CS}}$ or $\overline{\text{RD}}$ input should not be hard-wired low in this mode. Data cannot be read from the part during conversion because the on-chip latches are disabled when conversion is in progress. In applications where precise sampling is not critical, the $\overline{\text{CONVST}}$ pulse can be generated from a microprocessor $\overline{\text{WR}}$ line OR-gated with a decoded address. In some applications, depending on power supply turn-on time, the AD7870/AD7875/AD7876 may perform a conversion on power-up. In this case, the $\overline{\text{INT}}$ line will power-up low and a dummy read to the AD7870/AD7875/AD7876 will be required to reset the $\overline{\text{INT}}$ line before starting conversion.

Figure 9 shows the Mode 1 timing diagram for a 12-bit parallel data output format (12/$\overline{8}$/CLK = +5 V). A read to the ADC at the end of conversion accesses all 12 bits of data at the same time. Serial data is not available for this data output format.

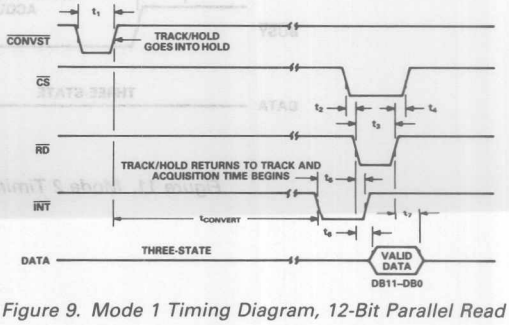

Figure 9. Mode 1 Timing Diagram, 12-Bit Parallel Read

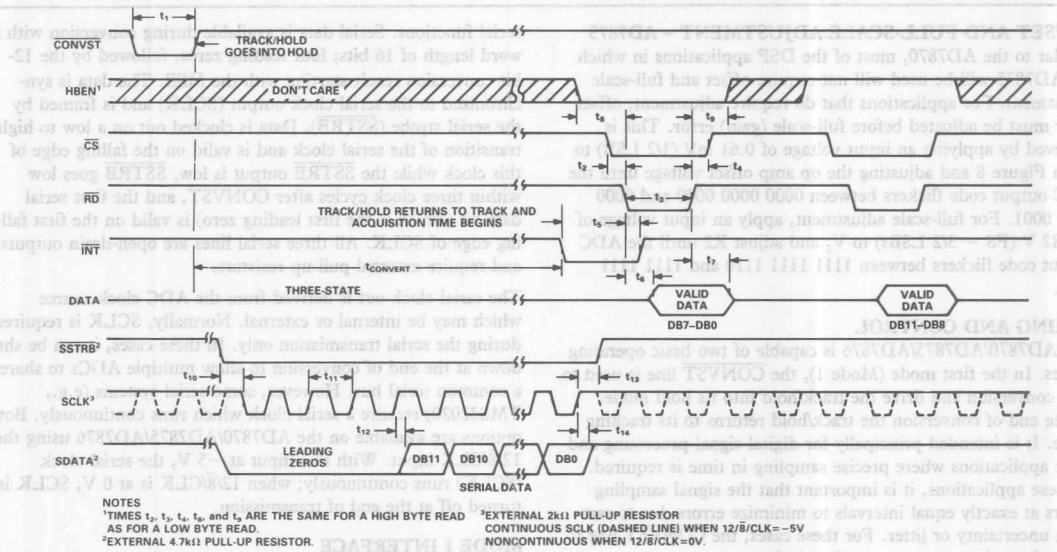

Figure 10. Mode 1 Timing Diagram, Byte or Serial Read

The Mode 1 timing diagram for byte and serial data is shown in Figure 10. $\overline{INT}$ goes low at the end of conversion and is reset high by the first falling edge of $\overline{CS}$ and $\overline{RD}$. This first read at the end of conversion can either access the low byte or high byte of data depending on the status of HBEN (Figure 10 shows low byte only for example). The diagram shows both a noncontinuously and a continuously running clock (dashed line).

MODE 2 INTERFACE

The second interface mode is achieved by hard wiring $\overline{CONVST}$ low and conversion is initiated by taking $\overline{CS}$ low while HBEN is low. The track/hold amplifier goes into the hold mode on the falling edge of $\overline{CS}$. In this mode, the $\overline{BUSY}$/$\overline{INT}$ pin assumes its $\overline{BUSY}$ function. $\overline{BUSY}$ goes low at the start of conversion, stays low during the conversion and returns high when the conversion is complete. It is normally used in parallel interfaces to drive the microprocessor into a WAIT state for the duration of conversion.

Figure 11 shows the Mode 2 timing diagram for the 12-bit parallel data output format (12/$\overline{8}$/CLK = +5 V). In this case, the ADC behaves like slow memory. The major advantage of this interface is that it allows the microprocessor to start conversion, WAIT and then read data with a single READ instruction. The user does not have to worry about servicing interrupts or ensuring that software delays are long enough to avoid reading during conversion.

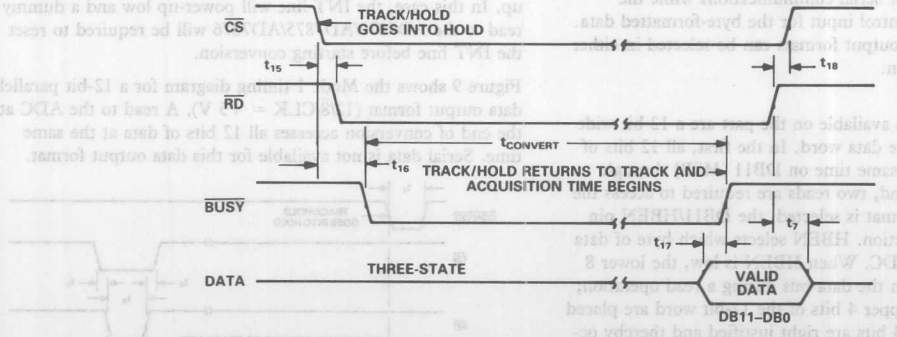

Figure 11. Mode 2 Timing Diagram, 12-Bit Parallel Read

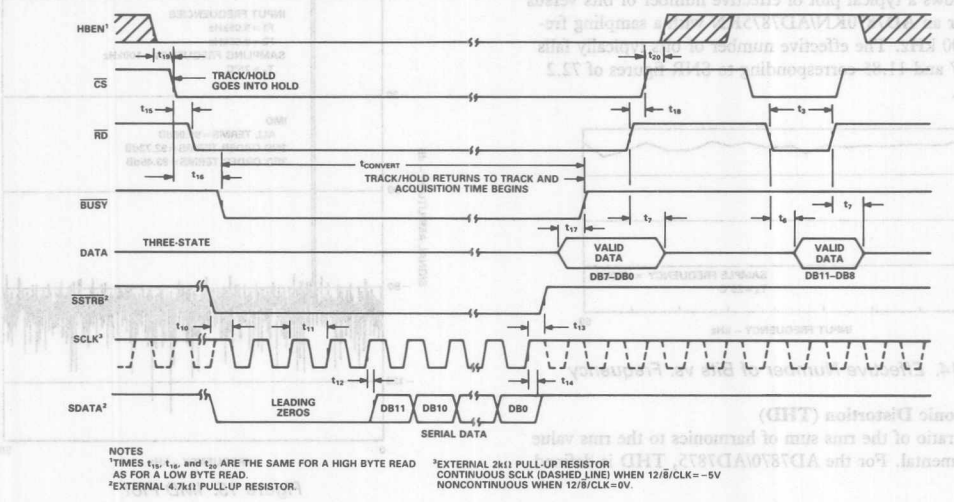

Figure 12. Mode 2 Timing Diagram, Byte or Serial Read

The Mode 2 timing diagram for byte and serial data is shown in Figure 12. For two-byte data read, the lower byte (DB0–DB7) has to be accessed first since HBEN must be low to start conversion. The ADC behaves like slow memory for this first read, but the second read to access the upper byte of data is a normal read. Operation of the serial functions is identical between Mode 1 and Mode 2. The timing diagram of Figure 12 shows both a noncontinuously and a continuously running SCLK (dashed line).

DYNAMIC SPECIFICATIONS

The AD7870 and AD7875 are specified and 100% tested for dynamic performance specifications as well as traditional dc specifications such as integral and differential nonlinearity. Although the AD7876 is not production tested for ac parameters, its dynamic performance is similar to the AD7870 and AD7875. The ac specifications are required for signal processing applications such as speech recognition, spectrum analysis and high speed modems. These applications require information on the ADC's effect on the spectral content of the input signal. Hence, the parameters for which the AD7870 and AD7875 are specified include SNR, harmonic distortion, intermodulation distortion and peak harmonics. These terms are discussed in more detail in the following sections.

Signal-to-Noise Ratio (SNR)

SNR is the measured signal-to-noise ratio at the output of the ADC. The signal is the rms magnitude of the fundamental. Noise is the rms sum of all the nonfundamental signals up to half the sampling frequency (FS/2) excluding dc. SNR is dependent upon the number of quantization levels used in the digitization process; the more levels, the smaller the quantization noise. The theoretical signal to noise ratio for a sine wave input is given by

$$SNR = (6.02N + 1.76)\ dB \qquad (1)$$

where N is the number of bits. Thus for an ideal 12-bit converter, SNR = 74 dB.

The output spectrum from the ADC is evaluated by applying a sine-wave signal of very low distortion to the V_{IN} input which is sampled at a 100 kHz sampling rate. A Fast Fourier Transform (FFT) plot is generated from which the SNR data can be obtained. Figure 13 shows a typical 2048 point FFT plot of the AD7870KN/AD7875KN with an input signal of 25 kHz and a sampling frequency of 100 kHz. The SNR obtained from this graph is 72.6 dB. It should be noted that the harmonics are taken into account when calculating the SNR.

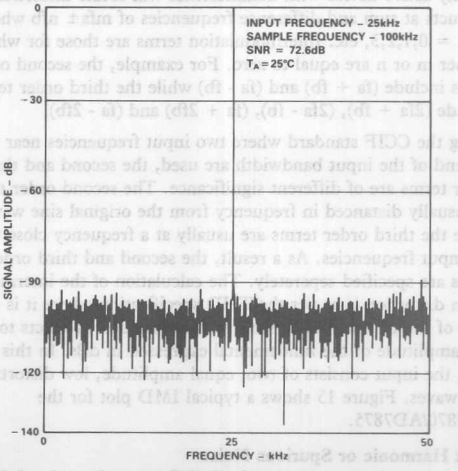

Figure 13. FFT Plot

Effective Number of Bits

The formula given in (1) relates the SNR to the number of bits. Rewriting the formula, as in (2), it is possible to get a measure of performance expressed in effective number of bits (N).

$$N = \frac{SNR - 1.76}{6.02} \qquad (2)$$

The effective number of bits for a device can be calculated directly from its measured SNR.

quency of 100 kHz. The effective number of bits typically falls between 11.7 and 11.85 corresponding to SNR figures of 72.2 and 73.1 dB.

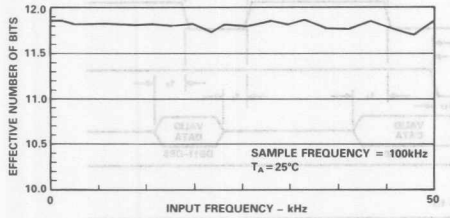

Figure 14. Effective Number of Bits vs. Frequency

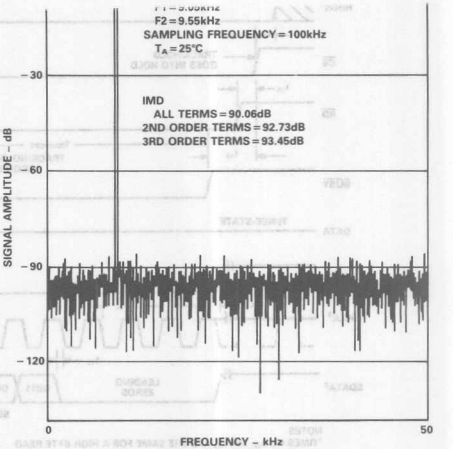

Figure 15. IMD Plot

Total Harmonic Distortion (THD)

THD is the ratio of the rms sum of harmonics to the rms value of the fundamental. For the AD7870/AD7875, THD is defined as

$$THD = 20\ log \frac{\sqrt{V_2^2+V_3^2+V_4^2+V_5^2+V_6^2}}{V_1}$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, V_5 and V_6 are the rms amplitudes of the second through the sixth harmonic. The THD is also derived from the FFT plot of the ADC output spectrum.

Intermodulation Distortion

With inputs consisting of sine waves at two frequencies, fa and fb, any active device with nonlinearities will create distortion products at sum and difference frequencies of mfa± nfb where m, n = 0,1,2,3, etc. Intermodulation terms are those for which neither m or n are equal to zero. For example, the second order terms include (fa + fb) and (fa - fb) while the third order terms include (2fa + fb), (2fa - fb), (fa + 2fb) and (fa - 2fb).

Using the CCIF standard where two input frequencies near the top end of the input bandwidth are used, the second and third order terms are of different significance. The second order terms are usually distanced in frequency from the original sine waves while the third order terms are usually at a frequency close to the input frequencies. As a result, the second and third order terms are specified separately. The calculation of the intermodulation distortion is as per the THD specification where it is the ratio of the rms sum of the individual distortion products to the rms amplitude of the fundamental expressed in dBs. In this case, the input consists of two, equal amplitude, low distortion sine waves. Figure 15 shows a typical IMD plot for the AD7870/AD7875.

Peak Harmonic or Spurious Noise

Peak harmonic or spurious noise is defined as the ratio of the rms value of the next largest component in the ADC output spectrum (up to FS/2 and excluding dc) to the rms value of the fundamental. Normally, the value of this specification will be determined by the largest harmonic in the spectrum, but for parts where the harmonics are buried in the noise floor the peak will be a noise peak.

AC Linearity Plot

When a sine wave of specified frequency is applied to the V_{IN} input of the AD7870/AD7875 and several million samples are taken, a histogram showing the frequency of occurrence of each of the 4096 ADC codes can be generated. From this histogram data it is possible to generate an ac integral linearity plot as shown in Figure 16. This shows very good integral linearity performance from the AD7870/AD7875 at an input frequency of 25 kHz. The absence of large spikes in the plot shows good differential linearity. Simplified versions of the formulae used are outlined below.

$$INL(i) = \left[\frac{V(i) - V(o)}{V(fs) - V(o)} \cdot 4096\right] - i$$

where INL(i) is the integral linearity at code i. V(fs) and V(o) are the estimated full-scale and offset transitions and V(i) is the estimated transition for the ith code.

V(i) the estimated code transition point is derived as follows:

$$V(i) = -A \cdot Cos\ \frac{[\pi \cdot cum(i)]}{N}$$

where A is the peak signal amplitude,

N is the number of histogram samples

and $cum(i) = \sum_{n=0}^{i} V(n)$ occurrences

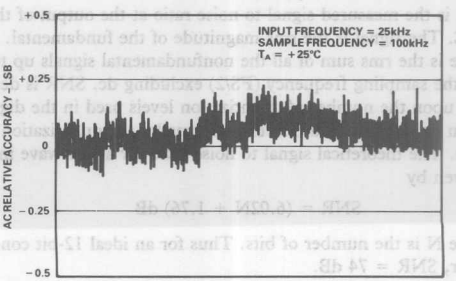

Figure 16. AC INL Plot

MICROPROCESSOR INTERFACE

The AD7870/AD7875/AD7876 has a wide variety of interfacing options. It offers two operating modes and three data-output formats. Fast data access times allow direct interfacing to most microprocessors including the DSP processors.

Parallel Read Interfacing

Figures 17 to 19 show interfaces to the ADSP-2100, TMS32010 and the TMS32020 DSP processors. The ADC is operating in Mode 1, parallel read for all three interfaces. An external timer controls conversion start asynchronously to the microprocessor. At the end of each conversion the ADC $\overline{BUSY/INT}$ interrupts the microprocessor. The conversion result is read from the ADC with the following instruction:

ADSP-2100: MR0 = DM(ADC)

TMS32010: IN D,ADC

TMS32020: IN D,ADC

MR0 = ADSP-2100 MR0 Register

D = Data Memory Address

ADC = AD7870/AD7875/AD7876 Address

Some applications may require that conversions be initiated by the microprocessor rather than an external timer. One option is to decode the $\overline{CONVST}$ signal from the address bus so that a write operation to the ADC starts a conversion. Data is read at the end of conversion as described earlier. Note, a read operation must not be attempted during conversion.

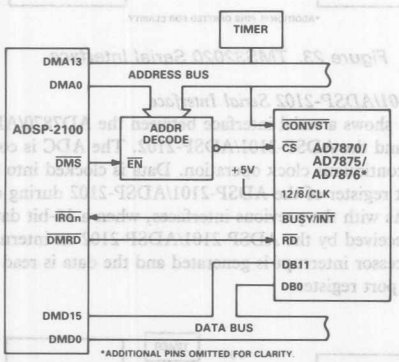

Figure 17. ADSP-2100 Parallel Interface

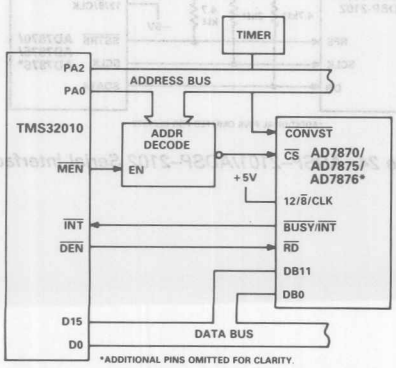

Figure 18. TMS32010 Parallel Interface

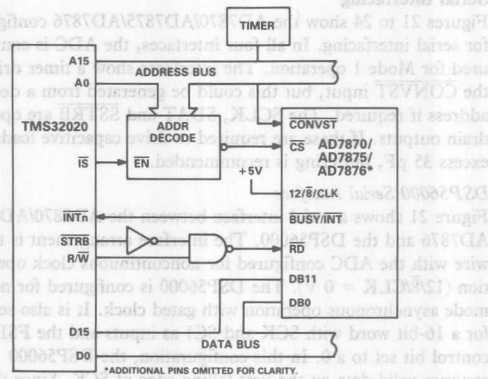

Figure 19. TMS32020 Parallel Interface

Two Byte Read Interfacing

68008 Interface

Figure 20 shows an 8-bit bus interface for the MC68008 microprocessor. For this interface, the 12/$\overline{8}$/CLK input is tied to 0 V and the DB11/HBEN pin is driven from the microprocessor least significant address bit. Conversion start control is provided by the microprocessor. In this interface example, a Move instruction from the ADC address both starts a conversion and reads the conversion result.

MOVEW ADC,DO

ADC = AD7870/AD7875/AD7876 address

D0 = 68008 D0 register

This is a two byte read instruction. During the first read operation, $\overline{BUSY}$ in conjunction with $\overline{CS}$ forces the microprocessor to WAIT for the ADC conversion. At the end of conversion the ADC low byte (DB7–DB0) is loaded into D15–D8 of the D0 register and the ADC high byte (DB15–DB7) is loaded into D7–D0 of the D0 register. The following Rotate instruction to the D0 register swaps the high and low bytes to the correct format.

R0L = 8, D0.

Note, while executing the two byte read instruction above, WAIT states are inserted during the first read operation only and not for the second.

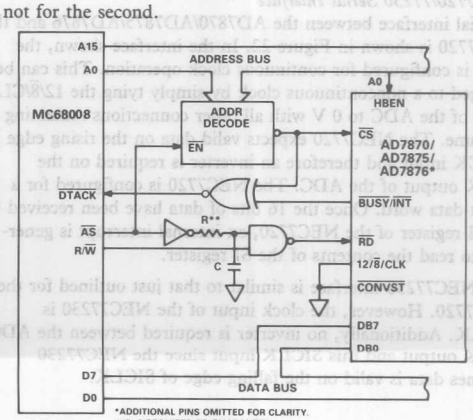

Figure 20. MC68008 Byte Interface

Serial Interfacing

Figures 21 to 24 show the AD7870/AD7875/AD7876 configured for serial interfacing. In all four interfaces, the ADC is configured for Mode 1 operation. The interfaces show a timer driving the $\overline{\text{CONVST}}$ input, but this could be generated from a decoded address if required. The SCLK, SDAT and $\overline{\text{SSTRB}}$ are open-drain outputs. If these are required to drive capacitive loads in excess 35 pF, buffering is recommended.

DSP56000 Serial Interface

Figure 21 shows a serial interface between the AD7870/AD7875/AD7876 and the DSP56000. The interface arrangement is two-wire with the ADC configured for noncontinuous clock operation (12/$\overline{8}$/CLK = 0 V). The DSP56000 is configured for normal mode asynchronous operation with gated clock. It is also set up for a 16-bit word with SCK and SC1 as inputs and the FSL control bit set to a 0. In this configuration, the DSP56000 assumes valid data on the first falling edge of SCK. Since the ADC provides valid data on this first edge, there is no need for a strobe or framing pulse for the data. SCLK and SDATA are gated off when the ADC is not performing a conversion. During conversion, data is valid on the SDATA output of the ADC and is clocked into the receive data shift register of the DSP56000. When this register has received 16 bits of data, it generates an internal interrupt on the DSP56000 to read the data from the register.

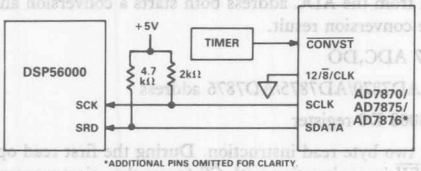

Figure 21. DSP56000 Serial Interface

The DSP56000 and AD7870/AD7875/AD7876 can also be configured for continuous clock operation (12/$\overline{8}$/CLK = −5 V). In this case, a strobe pulse is required by the DSP56000 to indicate when data is valid. The $\overline{\text{SSTRB}}$ output of the ADC is inverted and applied to the SC1 input of the DSP56000 to provide this strobe pulse. All other conditions and connections are the same as for gated clock operation.

NEC7720/77230 Serial Interface

A serial interface between the AD7870/AD7875/AD7876 and the NEC7720 is shown in Figure 22. In the interface shown, the ADC is configured for continuous clock operation. This can be changed to a noncontinuous clock by simply tying the 12/$\overline{8}$/CLK input of the ADC to 0 V with all other connections remaining the same. The NEC7720 expects valid data on the rising edge of its SCK input and therefore an inverter is required on the SCLK output of the ADC. The NEC7720 is configured for a 16-bit data word. Once the 16 bits of data have been received by the SI register of the NEC7720, an internal interrupt is generated to read the contents of the SI register.

The NEC77230 interface is similar to that just outlined for the NEC7720. However, the clock input of the NEC77230 is SICLK. Additionally, no inverter is required between the ADC SCLK output and this SICLK input since the NEC77230 assumes data is valid on the falling edge of SICLK.

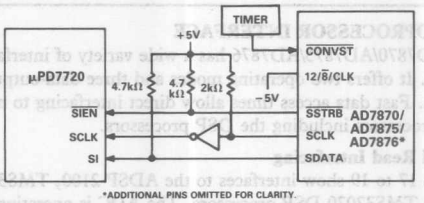

Figure 22. NEC7720 Serial Interface

TMS32020 Serial Interface

Figure 23 shows a serial interface between the AD7870/AD7875/AD7876 and the TMS32020. The AD7870/AD7875/AD7876 is configured for continuous clock operation. Note, the ADC will not interface correctly to the TMS32020 if the ADC is configured for a noncontinuous clock. Data is clocked into the data receive register (DRR) of the TMS32020 during conversion. As with the previous interfaces, when a 16-bit word is received by the TMS32020 it generates an internal interrupt to read the data from the DRR.

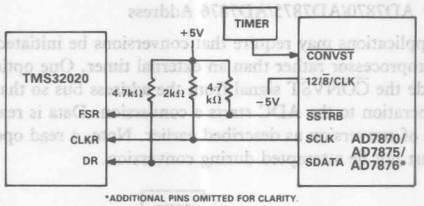

Figure 23. TMS32020 Serial Interface

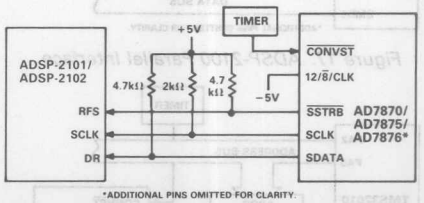
ADSP-2101/ADSP-2102 Serial Interface

Figure 24 shows a serial interface between the AD7870/AD7875/AD7876 and the ADSP-2101/ADSP-2102. The ADC is configured for continuous clock operation. Data is clocked into the serial port register of the ADSP-2101/ADSP-2102 during conversion. As with the previous interfaces, when a 16-bit data word is received by the ADSP-2101/ADSP-2102 an internal microprocessor interrupt is generated and the data is read from the serial port register.



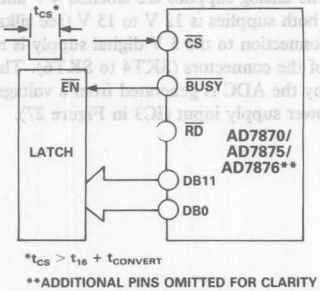


Figure 24. ADSP–2101/ADSP–2102 Serial Interface

STAND-ALONE OPERATION

The AD7870/AD7875/AD7876 can be used in its Mode 2, parallel interface mode for stand-alone operation. In this case, conversion is initiated with a pulse to the ADC $\overline{CS}$ input. This pulse must be longer than the conversion time of the ADC. The $\overline{BUSY}$ output is used to drive the $\overline{RD}$ input. Data is latched from the ADC DB0–DB11 outputs to an external latch on the rising edge of $\overline{BUSY}$.

*$t_{CS} > t_{16} + t_{CONVERT}$

**ADDITIONAL PINS OMITTED FOR CLARITY

Figure 25. Stand-Alone Operation

APPLICATION HINTS

Good printed circuit board (PCB) layout is as important as the overall circuit design itself in achieving high speed A/D performance. The designer has to be conscious of noise both in the ADC itself and in the preceding analog circuitry. Switching mode power supplies are not recommended as the switching spikes will feed through to the comparator causing noisy code transitions. Other causes of concern are ground loops and digital feedthrough from microprocessors. These are factors which influence any ADC, and a proper PCB layout which minimizes these effects is essential for best performance.

LAYOUT HINTS

Ensure that the layout for the printed circuit board has the digital and analog signal lines separated as much as possible. Take care not to run any digital track alongside an analog signal track. Guard (screen) the analog input with AGND.

Establish a single point analog ground (star ground) separate from the logic system ground at the AGND pin or as close as possible to the ADC. Connect all other grounds and the AD7870/AD7875/AD7876 DGND to this single analog ground point. Do not connect any other digital grounds to this analog ground point.

Low impedance analog and digital power supply common returns are essential to low noise operation of the ADC, so make the foil width for these tracks as wide as possible. The use of ground planes minimizes impedance paths and also guards the analog circuitry from digital noise. The circuit layout of Figures 30 and 31 have both analog and digital ground planes which are kept separated and only joined together at the AD7870/AD7875/AD7876 AGND pin.

NOISE

Keep the input signal leads to V_{IN} and signal return leads from AGND as short as possible to minimize input noise coupling. In applications where this is not possible, use a shielded cable between the source and the ADC. Reduce the ground circuit impedance as much as possible since any potential difference in grounds between the signal source and the ADC appears as an error voltage in series with the input signal.

DATA ACQUISITION BOARD

Figure 28 shows the AD7870/AD7875/AD7876 in a data acquisition circuit. The corresponding printed circuit board (PCB) layout and silkscreen are shown in Figures 29 to 31. The board layout has three interface ports: one serial and two parallel. One of the parallel ports is directly compatible with the ADSP-2100 evaluation board expansion connector.

The only additional component required for a full data acquisition system is an antialiasing filter. There is a component grid provided near the analog input on the PCB which may be used for such a filter or any other input conditioning circuitry. To facilitate this option there is a shorting plug (labelled LK1 on the PCB) on the analog input track. If this shorting plug is used, the analog input connects to the buffer amplifier driving the ADC; if this shorting plug is omitted, a wire link can be used to connect the analog input to the PCB component grid.

INTERFACE CONNECTIONS

There are two parallel connectors labeled SKT4 and SKT6 and one serial connector labeled SKT5. A shorting plug option (LK3 in Figure 28) on the ADC 12/$\overline{8}$/CLK input configures the ADC for the appropriate interface (see Pin Function Description).

SKT6 is a 96-contact (3-ROW) Eurocard connector which is directly compatible with the ADSP-2100 Evaluation Board Prototype Expansion Connector. The expansion connector on the ADSP-2100 has eight decoded chip enable outputs labeled $\overline{ECE1}$ to $\overline{ECE8}$. $\overline{ECE6}$ is used to drive the ADC $\overline{CS}$ input on the data acquisition board. To avoid selecting on board RAM sockets at the same time, LK6 on the ADSP-2100 board must be removed. In addition, the ADSP-2100 expansion connector has four interrupts labelled $\overline{EIRQ0}$ to $\overline{EIRQ3}$. The ADC $\overline{BUSY/INT}$ output connects to $\overline{EIRQ0}$. There is a single wait state generator connected to EDMACK to allow the ADC to interface to the faster versions of the ADSP-2100.

SKT4 is a 26-way (2-ROW) IDC connector. This connector contains all the signal contacts as SKT6 with the exception of EDMACK which is connected to SKT6 only. It also contains decoded R/$\overline{W}$ and $\overline{STRB}$ inputs which are necessary for TMS32020 interfacing. The SKT4 pinout is shown in Figure 26.

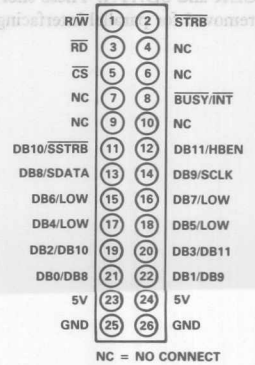

Figure 26. SKT4, IDC Connector Pinout

SKT5 is a 9 way D-type connector which is meant for serial interfacing only. An inverted DB9/SCLK output is also provided on this connector for systems which accept data on a rising clock edge. The SKT5 pinout is shown in Figure 27.

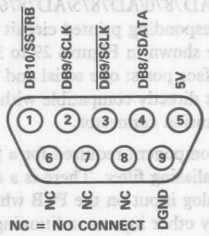

Figure 27. SKT5, D-Type Connector Pinout

SKT1, SKT2 and SKT3 are three BNC connectors which provide input connections for the analog input, the $\overline{\text{CONVST}}$ input and an external clock input. The use of an external clock source is optional, there is a shorting plug (LK2) on the ADC CLK input which must be connected to either −5 V (for the ADCs own internal clock) or to SKT3.

POWER SUPPLY CONNECTIONS

The PCB requires two analog power supplies and one 5 V digital supply . The analog supplies are labelled V+ and V−, and the range for both supplies is 12 V to 15 V (see silkscreen in Figure 29). Connection to the 5 V digital supply is made through any of the connectors (SKT4 to SKT6). The −5 V supply required by the ADC is generated from a voltage regulator on the V− power supply input (IC3 in Figure 27).

SHORTING PLUG OPTIONS

There are seven shorting plug options which must be set before using the board. These are outlined below:

LK1 Connects the analog input to a buffer amplifier. The analog input may also be connected to a component grid for signal conditioning.

LK2 Selects either the ADC internal clock or an external clock source.

LK3 Configures the ADC 12/$\overline{8}$/CLK input for the appropriate serial or parallel interface.

LK4 Connects the ADC $\overline{\text{RD}}$ input directly to the two parallel connectors or to a decoded $\overline{\text{STRB}}$ and R/$\overline{\text{W}}$ input. This shorting plug setting depends on the microprocessor e.g., the TMS32010 has a separate $\overline{\text{RD}}$ output while the TMS32020 has $\overline{\text{STRB}}$ and R/$\overline{\text{W}}$ outputs.

LK5– LK7 Connect the pull-up resistors R3, R4 and R5 to $\overline{\text{SSTRB}}$, SCLK and SDATA. These shorting plugs should be removed for parallel interfacing.

COMPONENT LIST

IC1	AD711 Op Amp
IC2	AD7870/AD7875/AD7876 Analog-to-Digital Converter
IC3	MC79L05 −5 V Regulator
IC4	74HC00 Quad NAND Gate
IC5	74HC74 Dual D-Type Flip Flop
C1, C3, C5, C7, C9, C11	10 μF Capacitors
C2, C4, C6, C8, C10, C12	0.1 μF Capacitors
R1, R2	10 kΩ Pull-Up Resistors
R3*, R5*	4.7 kΩ Pull-Up Resistors
R4*	2 kΩ Pull-Up Resistor
LK1, LK2 LK3, LK4 LK5, LK6, LK7	Shorting Plugs

LC²MOS
Complete 14-Bit, Sampling ADCs
AD7871/AD7872

FEATURES
- Complete Monolithic 14-Bit ADC
- 2s Complement Coding
- Parallel, Byte and Serial Digital Interface
- 80 dB SNR at 10 kHz Input Frequency
- 57 ns Data Access Time
- Low Power—50 mW typ
- 83 kSPS Throughput Rate
- 16-Lead SOIC (AD7872)

APPLICATIONS
- Digital Signal Processing
- High Speed Modems
- Speech Recognition and Synthesis
- Spectrum Analysis
- DSP Servo Control

FUNCTIONAL BLOCK DIAGRAMS

GENERAL DESCRIPTION

The AD7871 and AD7872 are fast, complete, 14-bit analog-to-digital converters. They consist of a track/hold amplifier, successive-approximation ADC, 3 V buried Zener reference and versatile interface logic. The ADC features a self-contained, laser trimmed internal clock, so no external clock timing components are required. The on-chip clock may be overridden to synchronize ADC operation to the digital system for minimum noise.

The AD7871 offers a choice of three data output formats: a single, parallel, 14-bit word; two 8-bit bytes or a 14-bit serial data stream. The AD7872 is a serial output device only. The two parts are capable of interfacing to all modern microprocessors and digital signal processors.

The AD7871 and AD7872 operate from ±5 V power supplies, accept bipolar input signals of ±3 V and can convert full power signals up to 41.5 kHz.

In addition to the traditional dc accuracy specifications, the AD7871 and AD7872 are also fully specified for dynamic performance parameters including distortion and signal-to-noise ratio.

Both devices are fabricated in Analog Devices' LC²MOS mixed technology process. The AD7871 is available in 28-pin plastic DIP, hermetic DIP and PLCC packages. The AD7872 is available in 16-pin plastic and hermetic DIP packages or 16-lead SOIC.

PRODUCT HIGHLIGHTS

1. Complete 14-Bit ADC on a Chip.
2. Dynamic Specifications for DSP Users.
3. Low Power.

Parameter	J, A Versions[1]	K, B Versions[1]	T Version[1]	Units	Test Conditions/Comments
DYNAMIC PERFORMANCE[2]					
Signal to Noise Ratio[3] (SNR) @ +25°C	80	80	79	dB min	V_{IN} = 10 kHz Sine Wave
T_{min} to T_{max}	80	80	79	dB min	SNR is Typically 82 dB for $<V_{IN}<$41.5 kHz;
Total Harmonic Distortion (THD)	−86	−90		dB max	V_{IN} = 10 kHz Sine Wave
			−85	dB typ	
Peak Harmonic or Spurious Noise	−86	−90		dB max	V_{IN} = 10 kHz.
			−85	dB typ	
Intermodulation Distortion (IMD)					
Second Order Terms	−86	−90		dB max	fa = 9 kHz, fb = 9.5 kHz, f_{SAMPLE} = 50 kHz
			−85	dB typ	
Third Order Terms	−86	−90		dB max	fa = 9 kHz, fb = 9.5 kHz, f_{SAMPLE} = 50 kHz
			−85	dB typ	
Track/Hold Acquisition Time	2	2	2	μs max	
DC ACCURACY					
Resolution	14	14	14	Bits	
Minimum Resolution for Which					
No Missing Codes Are Guaranteed	14	14	14	Bits	
Integral Nonlinearity @ +25°C		±1/2	±1/2	LSB typ	
Integral Nonlinearity		±1	±1	LSB max	
Bipolar Zero Error	±12	±12	±12	LSB max	
Positive Gain Error[4]	±12	±12	±12	LSB max	
Negative Gain Error[4]	±12	±12	±12	LSB max	
ANALOG INPUT					
Input Voltage Range	±3	±3	±3	Volts	
Input Current	±500	±500	±500	μA max	
REFERENCE OUTPUT					
REF OUT @ +25°C	2.99/3.01	2.99/3.01	2.99/3.01	V min/V max	
T_{min} to T_{max}	2.98/3.02	2.98/3.02	2.98/3.02	V min/V max	
REF OUT Tempco		±40	±40	ppm/°C max	Typically 35 ppm
Reference Load Sensitivity					
(ΔREF OUT/ΔI)	±1	±1	±1	mV max	Reference Load Current Change (0–500 μA); Reference Load Should Not Be Changed During Conversion
LOGIC INPUTS					
Input High Voltage, V_{INH}	2.4	2.4	2.4	V min	V_{DD} = 5 V ± 5%
Input Low Voltage, V_{INL}	0.8	0.8	0.8	V max	V_{DD} = 5 V ± 5%
Input Current, I_{IN}	±10	±10	±10	μA max	V_{IN} = 0 V to V_{DD}
Input Current (14/8/CLK Input Only)	±10	±10	±10	μA max	V_{IN} = V_{SS} to V_{DD}
Input Capacitance, C_{IN}[5]	10	10	10	pF max	
LOGIC OUTPUTS					
Output High Voltage, V_{OH}	4.0	4.0	4.0	V min	I_{SOURCE} = 40 μA
Output Low Voltage, V_{OL}	0.4	0.4	0.4	V max	I_{SINK} = 1.6 mA
DB13 – DB0					
Floating-State Leakage Current	10	10	10	μA max	
Floating-State Output Capacitance[5]	15	15	15	pF max	
CONVERSION TIME					
External Clock	10	10	10	μs max	
Internal Clock	10.5	10.5	10.5	μs max	The Internal Clock Has a Nominal Value of 2 MHz
POWER REQUIREMENTS					
V_{DD}	+5	+5	+5	V nom	±5% for Specified Performance
V_{SS}	−5	−5	−5	V nom	±5% for Specified Performance
I_{DD}	13	13	13	mA max	Typically 6 mA
I_{SS}	6	6	6	mA max	Typically 4 mA
Power Dissipation	95	95	95	mW max	Typically 50 mW

NOTES

[1]Temperature ranges are as follows: J, K versions, 0°C to +70°C; A, B versions, −40°C to +85°C; T version; −55°C to +125°C.

[2]V_{IN} = ±3 V.

[3]SNR calculation includes distortion and noise components.

[4]Measured with respect to internal reference.

[5]Sample tested @ +25°C to ensure compliance.

Specifications subject to change without notice.

TIMING CHARACTERISTICS[1, 2] (V_{DD} = +5 V ± 5%, V_{SS} = −5 V ± 5%, AGND = DGND = 0 V. See Figures 9, 10, 11 and 12.)

Parameter	Limit at T_{min}, T_{max} (J, K, A, B Versions)	Limit at T_{min}, T_{max} (T Version)	Units	Conditions/Comments
t_1	50	50	ns min	$\overline{CONVST}$ Pulse Width
t_2	0	0	ns min	$\overline{CS}$ to $\overline{RD}$ Setup Time (Mode 1)
t_3	**60**	**75**	ns min	$\overline{RD}$ Pulse Width
t_4	0	0	ns min	$\overline{CS}$ to $\overline{RD}$ Hold Time (Mode 1)
t_5	70	70	ns min	$\overline{RD}$ to $\overline{INT}$ Delay
t_6[3]	**57**	**70**	ns max	Data Access Time after $\overline{RD}$
t_7[4]	5	5	ns min	Bus Relinquish Time after $\overline{RD}$
	50	**50**	ns max	
t_8	0	0	ns min	HBEN to $\overline{RD}$ Setup Time
t_9	0	0	ns min	HBEN to $\overline{RD}$ Hold Time
t_{10}	100	100	ns min	$\overline{SSTRB}$ to SCLK Falling Edge Setup Time
t_{11}[5]	440	440	ns min	SCLK Cycle Time
t_{12}[6]	155	155	ns max	SCLK to Valid Data Delay. C_L = 35 pF
t_{13}	140	150	ns max	SCLK Rising Edge to $\overline{SSTRB}$
	20	20	ns min	
t_{14}	4	4	ns min	Bus Relinquish Time after SCLK
	100	100	ns max	
t_{15}	60	60	ns min	$\overline{CS}$ to $\overline{RD}$ Setup Time (Mode 2)
t_{16}	120	120	ns max	$\overline{CS}$ to $\overline{BUSY}$ Propagation Delay
t_{17}[3]	200	200	ns min	Data Setup Time Prior to $\overline{BUSY}$
t_{18}	0	0	ns min	$\overline{CS}$ to $\overline{RD}$ Hold Time (Mode 2)
t_{19}	0	0	ns min	HBEN to $\overline{CS}$ Setup Time
t_{20}	0	0	ns min	HBEN to $\overline{CS}$ Hold Time

NOTES

[1]Timing Specifications in **bold print** are 100% production tested. All other times are sample tested at +25°C to ensure compliance. All input signals are specified with tr = tf = 5 ns (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

[2]Serial timing is measured with a 4.7 kΩ pull-up resistor on SDATA and $\overline{SSTRB}$ and a 2 kΩ pull-up resistor on SCLK. The capacitance on all three outputs is 35 pF.

[3]t_6 and t_{17} are measured with the load circuits of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.

[4]t_7 is derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 2. The measured number is then extrapolated back to remove the effects of charging or discharging the 50 pF capacitor. This means that the time, t_7, quoted in the Timing Characteristics is the true bus relinquish time of the part and is independent of bus loading.

[5]SCLK mark/space ratio (measured from a voltage level of 1.6 V) is 40/60 to 60/40.

[6]SDATA will drive higher capacitive loads, but this will add to t_{12} since it increases the external RC time constant (4.7 kΩ//C_L) and hence the time to reach 2.4 V.

Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS*

V_{DD} to AGND . . . . . −0.3 V to +7 V
V_{SS} to AGND . . . . . +0.3 V to −7 V
AGND to DGND . . . . . −0.3 V to V_{DD} + 0.3 V
V_{IN} to AGND . . . . . V_{SS} − 0.3 V to V_{DD} + 0.3 V
REF OUT, C_{REF} to AGND . . . . . 0 V to V_{DD}
Digital Inputs to DGND . . . . . −0.3 V to V_{DD} + 0.3 V
Digital Outputs to DGND . . . . . −0.3 V to V_{DD} + 0.3 V
Operating Temperature Range
